

## Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

## Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
- + *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

## Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter <http://books.google.com> durchsuchen.

# CONTENTS

VOL. XVIII., NEW SERIES. VOL. LXIX., OLD SERIES.  
JULY TO DECEMBER, 1874.

## A

Abortive treatment of boils, 345  
Academy of Medicine, Paris, 412  
Accident ambulances, 275  
Accident to a medical man, 364  
Acclimatisation of *Iperacuanha*, 487  
Acland, H. W., M.D., F.R.S., on the influence of social and sanitary conditions on religion, 327  
Action of drugs, 398, 421, 439, 461, 504, 529, 552  
Action of *veratrum viride* upon the circulation, 332  
Action against an insurance company, 205  
Action of alkaloids on albuminoid substances, 258  
Acute articular rheumatism, 346  
Address in obstetric medicine, by Matthews Duncan, M.D., 158, 174  
Adipocera, 290  
Adulteration law, 78  
Adulteration Act, 337  
Adulteration of beer, 116  
Adulteration defined, 553  
Alcoholism among the easy classes, 381  
Allen on medical problems of the day, 1, 19  
Allingham, W., F.R.C.S., on the treatment of fistulous sinuses by means of the elastic ligature, 409, 521  
Alopecia areata at the Pathological Society, 509  
American Medical Association, 184  
American communications, 200, 218  
American debate on Cancer, 215  
American mineral waters, 310  
Anæsthesia during sleep, 163  
Anæsthesia by chloral and chloroform, 510  
Analysts' certificates, 468  
Anatomy, human, lectures on, by Walter Rivington, F.R.C.S., 9, 38, 110  
Anderson, the late Dr., 442  
Anderson's University, Glasgow, 95  
Andrews on ozone, 56  
Aneurism mistaken for asthma, 345  
Aneurism of the abdominal aorta and heart, 571  
Animals as motor powers, 533  
Anstie, Dr., the late, 279, 290, 339  
Antagonism of remedies, 509  
Antiseptic method after Professor Lister, 511  
Ant-cloud, 133

Anti-vaccinators, 228  
Aphthous stomatitis communicated to man, 345  
Apothecaries' Company, the, 7  
Application for burns, 345  
Application of autoplasty by the flap method for the cure of salivary fistula, by J. Morgan, F.R.C.S.I., 179  
Appropriation of celebrated names by quacks, 162  
A practical treatise on eczema, 559  
"A pressing subject," 96  
Army medical service, 199, 235  
Arteries, their pathology in Bright's disease, 13  
Artificial production of actinism, 382  
Artificial butter, 534  
A second note on wine, 118  
Assessment of salaries by the Local Government Board, 272  
Asthma treated with subcutaneous injection of chloral, 165  
Auscultation, the earliest record of, 438  
Austin, Dr. R., estimation of total nitrogen in urea, 13, 119

## B

Barraclough, G., M.A. (Cantab), medical science and medical teaching, 83, 105, 129, 177  
Bathing quarters on the Straits of Dover, 296, 285  
Bent knee, the cure of, and the immediate treatment of contracted joints, by J. Morgan, M.D., F.R.C.S., 431, 478  
Berry, Mr. W., M.R.C.S., on railway cases, 184  
Black, Campbell, M.D., on Bright's disease, with special reference to pathology and treatment, 81, 104, 147, 169  
Blood-drinkers, 465  
Bloodless surgery, 357  
Bolds, 352  
Brighton, the drainage of, 267  
Bright's disease, lectures on, by Campbell Black, M.D., 81, 104, 147, 169  
British Medical Association, 165, 185, 202  
Burnes, A. G., M.B., on hydrate of chloral, 86  
Burnes, A. G., M.D., strychnine as an antidote to opium poisoning, 333

Byrne, M.R.C.S.E., on a case of twin-birth, compound presentation of second child, 131

## C

Cæsarian section and the elastic sutures, 533  
Cambridge certificate in State medicine, 509  
Cambridge University, 362  
Carnivorous plants, 274  
Carotid artery, successful case of ligature, by R. H. Supple, M.B., 434  
Cases in practice, reported by Dr. J. W. Martin, 374, 433  
Cerebral derangement, phases of, by Surgeon-Major Hogg, R.A., 332  
Chair of Chemistry in Dublin University, 318  
Change of anatomical nomenclature, 427  
Charge against a parish surgeon, 206  
Charity organisation, 330  
Charity voting reform, 465  
Charcot, Dr., on Bright's disease, 534  
Chemistry in its relations to therapeutics, by W. Handzel Griffiths, Ph.D., 393  
Chinese opium-eaters, 554  
Chloroform in eclampsia infantum, 403  
Chloral, injurious effect by the continued exhibition of, by Dr. F. M. Luther, 523  
Chlorhydrate of trimethylamine in rheumatic fever, 345  
Cholera in Vienna, 163  
Cholera, its ætiology, contagiousness, and treatment, by W. B. Mueset, M.D., 369, 455, 547, 564  
Cholera in France from 1854 to 1855, 26  
Cherley case of malaprazia, the, 207  
Chuckerbutty, G. S., M.D., 362  
Clark, A., F.R.C.S., introductory address at the Middlesex Hospital, 310  
Clinical memoranda, 566  
Climb system, the, 221  
College of Surgeons, 28  
Comparative healthiness of English watering places, 224  
Compression in hydrarthrosis of knee-joint, 536

Compulsory fixing of sanitary salaries, 535  
Congenital absence of the corpus callosum, 465  
Conjoint examination scheme, 483  
Contamination of aerated waters, 306  
Contagion in board schools, 427  
Conversazione at the Royal College of Physicians, 32  
Cookery, 9  
Coroners, 409  
Correlation of medical poor relief and public health administration, W. H. Rumsey, M.D., 197  
Cost of disease in Sheffield, 423  
Cough, 135  
Court hospitalities to the profession, 73  
Counter practice, 445

## CORRESPONDENCE.

Bathing quarters on the Straits of Dover, 296, 285  
Compulsory sanitary duty, 78  
Criminal abortion, 277  
Croup, 121, 166  
Dr. C. West and the British Medical Association, 64, 295  
Dr. Lyon Playfair on health, 323  
Dr. Lankester and the corporations, by Edwards Crisp, M.D., 471  
Estimation of total nitrogen in urea, 13, 55  
Estimation of total nitrogen in urine, 119, 143  
Examination for the Army Medical Service, 76  
Examination reform in the Irish College of Surgeons, 101, 130  
Harveian oration, the, 51, 75  
Homœopathy and the profession, 428  
Hospital Saturday, 493, 415  
Irish Poor-law medical officers, 54  
Law for lawyers versus the law for doctors, 344  
Medical baronetcy in Ireland, 12  
Medical men and the commission of the peace, 78  
Medical ethics, by Themus, 494  
New theory on the preservation of the coats of the stomach from the effects of the gastric juice, 451  
Pathology of arteries in Bright's disease, 13, 82, 56

Pen vaccinator, by George Edward Nicholls, M.D., 472  
Pharmacy in Ireland, 13, 55  
Possible arrest of hydrophobia or water-ahy, 405  
Practice in America, 55  
Public Health Bill, Ireland, 101, 322  
Railway cases, a suggestion, 188  
Relations of the profession towards homoeopathy, 281, 295  
Reports of visitors on the Irish College of Surgeons, 76  
Reports of visitors on the examination of the Royal College of Surgeons, Ireland, 77  
Study of life: a medical review, 383  
The Folkestone water, 78  
The theory of counter-irritation, 119, 183, 209  
The medical profession, supply and demand, 143  
The pen vaccinator, by R. Harvey Hilliard, M.D., 493  
The Contagious Diseases Acts, by Dr. Bell Taylor, 516  
The College of Physicians of Ireland, 559  
Typhus fever, by Alexander Lane, M.D., 537  
Uremic convulsions simulating epilepsy, 344  
  
Cremation, practical, 274  
Cremation, 383  
Cremation in Germany, 445  
Cremation as a cause of Indian cholera, 466  
Criminal lunatics, 183  
Croup, 121, 166  
Croup, case of, by John Leonard Kealy, L.R.C.S., 434  
Cutaneous medicine, 442  
Cystic goitre cured by the drainage tube, 79

D

Dangers of anaesthetics, 557  
Davis, N. S., M.D., report on physiology, materia medica, and the practice of medicine, 200  
Deadly medicine, a, 446  
Deaths in Irish workhouses, 115  
Deaths from methylene and chloroform, 557  
Death from chloroform, 573  
Deformities, lectures on the nature and treatment of, by Dr. Omsby, 179, 191, 250, 231, 329, 352, 413, 454  
Degrees in State medicine, 508  
Depths of the ocean, 207  
Destination of the newly-qualified surgeon, 335  
Determination of sex ante-partum, 371  
Determination of sex in utero, 381  
Diabetes, treatment of, 555  
Diapedesis, 160  
Diagnosis of death, 487  
Dickinson, Dr. W. H., introductory address at St. George's Hospital, 310  
Differentiation of intestinal invagination, 588  
Dignified, 487  
Diminution of infant vaccination in Ireland, 139  
Distribution of the Hospital Sunday Fund, 206  
Doctors of the olden times, 205  
Doctor, the, in the witness box, 269  
Double aortic aneurism, 515  
Dr. Edmunds' post, 571  
Drug sophistication, 29  
Drunkness as a cause of insanity, 513  
Drysdale, reports on syphilis, 16, 86, 125, 172, 194, 260, 283, 324, 371, 456, 544  
Drysdale, Dr. John, theory of counter-irritation, 119, 209  
Dublin main drainage, 182  
Dublin sewage, 289  
Dublin corporation and its sanitary duty, 471  
Dugong oil, by Dr. McGrigor Croft, 33  
Dugong oil, 32  
Duncan, Matthews, M.D., address in obstetric medicine, 153, 174  
Dwellings of the poor, 444  
Dysmenorrhoea, remedy for, 509

E

Edinburgh chair of physiology, 71  
Edinburgh University, 445  
Effect of enlarged thymus, 161  
Effects of the scarlatina epidemic upon the death-rate, 557  
Eichorst on hereditary transmissibility of progressive muscular atrophy, 57  
Elastic ligature in the treatment of fistulous sinuses, 480, 499, 521  
Elastic compression after Eschmarch's method, 511  
Elimination of alcohol, 291  
Emigration service, 240  
English provincial medical schools, 246  
English conjoint examination, 96  
Epidermic grafts from the skin of the rabbit, 406  
Epigram on cremation, by Dr. W. Boyd Maahet, 450  
Epilepsies, the scientific and empirical investigation of, by Hughlings Jackson, M.D., 325, 347, 389, 409, 476, 497, 520  
Ergotine injections in prolapsus ani, 359  
Estimation of total nitrogen in urea, by R. Austin, M.D., 13, 119  
Estimation of total nitrogen in urea, by Professor Emerson Reynolds, 55, 143  
European communities for young surgeons, 210  
Examinations at the College of Surgeons, 112  
Exhibition of photomezzotinto portraits, 72  
Experimental researches on the movements of the uterus, 168  
Expenditure in Irish lunatic asylums, 631  
Exposing the quacks, 387

F

Failure of the conjoint scheme for England, 96  
Fallacious evidence of the senses, 363  
Faults in lunacy laws, 508  
Fees to coroners, 133  
Female doctors, 135  
Fenwick, Dr. S., introductory address at the London Hospital, 303  
Ferrier, Dr. D., introductory address at King's College, 308  
Fever in London, 468  
Fever, alarming outbreak of, 345  
First place by competition, 367  
Fish of paradise, 364  
Fistulous sinuses, their treatment by the elastic ligature, by W. Allingham, F.R.C.S., 480, 499, 521  
Flogging schoolmasters, 74, 114  
Food of plants and animals, 247  
Fothergill, Dr. J. Milner, the pathology of arteries in Bright's disease, 14, 56  
Fracture of skull followed by hernia cerebri, by John G. Adamson, A.M., M.D., 565  
Fraudulent musk, 485  
Free phosphorus in medicine, by J. A. Thompson, 561  
French Association for the Advancement of Science, 133  
Functions of the brain, 133  
Fungous origin of erysipelas, 406

G

General Medical Council, 7, 93  
General Council of Medical Education and Registration, 1874, 41, 60, 93  
Genesis and propagation of cholera, 270  
German Sanitary Congress, 317  
Gibbons, Henry, M.D., illustrations of the literature of quackery, 213  
Goitre, exophthalmic, 510  
Goitre and cretinism, how developed, by Dr. Wilson, 293  
Gonorrhoea, complications of, 503  
Gordon, Surgeon-General, C.B., notes on Paris besieged, 37

Gordon, Surgeon-General, C.B., remarks on the use and abuse of spirits and fermented drinks in armies during war, 149, 192  
Gray, Dr., the late, of Broadmoor Asylum, 93  
Griffiths, Dr. Handzel, chemistry in its relation to therapeutics, 393  
Griffiths, Dr. Handzel, lessons on prescriptions and the art of prescribing, 265, 341, 375  
Growth of specialties, 273  
Gull, Sir W., Bart., introductory address at Guy's Hospital, 306

H

Hampstead Hospital, 445, 466  
Harvelian oration, the, 54, 75, 295  
Hay fever sufferers, 443  
Heart in poisoning by arsenic, 9  
Health of Kensington, 362  
Hilliard and "pen" vaccinator, 338  
Hinged short forceps, 115  
Hogg, Surgeon-Major, on phases of cerebral derangement, 332  
Hogg, Mr. Jabez, on the Folkestone water, 78  
Homoeopathic definition of a drug, 384  
Homoeopathic dosage, 427  
Homoeopathic surgery, 443  
Hospital Sunday, 23  
Hospital Saturday Fund, 205, 275, 380, 407, 515, 561  
Hospital Sunday in Dublin, 289  
Hospital Sunday in Devonshire, 494  
Human anatomy, lectures on, by Walter Livingston, F.R.C.S., 9, 33, 110, 523  
Human flesh, the taste of, 533  
Hunterian Museum, the, 30  
Hunterian Society, 317  
Hydatid cyst, 503  
Hydrocele, the cure of by electro-puncture, 533  
Hydrophobia, 183, 294  
Hydrophobia, possible arrest of, by Henry MacCormac, M.D., 405

HOSPITAL REPORTS.

Cashel Union Hospital: Bloodless operating, under the care of Dr. Laffan, 91, 109; entropion, 182; staphylocoma, 182; exsusion of eyeball, 182; grafting, 397; cut-throat, 397; significance of albuminuria, 398; fracture of the patella, 398; fever noteleate, 398; epithelioma, 398; stricture of the urethra, 398; hydrocele of the neck, 398; fistula in ano, 398; fistula in the neck and thigh, 437  
Charing Cross Hospital: A supplementary spleen, 377  
General Hospital, Douglas, Isle of Man: Cases in hospital practice, by T. A. Woods, Esq., M.B. Dub., 377  
London Hospital: Cases of chronic mercurial poisoning from the use of pink and red vulcanite in artificial gums, with remarks and experiments, by W. Bathurst Woodman, M.D., 502  
Meath Hospital: Remarkable case of trismus treated by Rawdon Macnamara, M.D., 312  
Metropolitan Free Hospital: cases under the care of Dr. C. R. Drysdale: Albuminuria syphilitica, 90; hereditary syphilitic laryngitis, 90; alopecia areata, 90; epilepsy from tickling, 90; dysentery and ipsecosmum, 436, 566  
North London Consumption Hospital, under the care of Dr. C. R. Drysdale: Case of somnambulism, 378  
Richmond Hospital, Dublin: Scald of the glottis followed by oedema — tracheotomy — recovery; under the care of Prof. Stokes, 377

Royal London Ophthalmic Hospital: Glaucoma by iridectomy of the left eye, under the care of Mr. Couper, 523  
St. Vincent's Hospital, Dublin, under the care of Dr. Mapother: Oxalate of lime calculus — lithotomy — urethral stricture established on seventh day, 219  
Tyrone Infirmary: Removal of tumour by the use of Eschmarch's apparatus, under the care of Dr. E. C. Thompson, 532  
Westmeath Infirmary: Successful operation for strangulated inguinal hernia, 264

I

Idiopathic tetanus treated successfully, 414  
Illustrations of the literature of quackery, by H. Gibbons, M.D., 215

ILLUSTRATIONS.—Autoplasty, by J. Morgan, F.R.C.S., 180; spinal supports, by Dr. Ormsby, 232; appliances for lateral curvature of the spine, by Dr. Ormsby, 420; instrument for wry neck, 353; retraction after severe burns, before and after operation, 354; new pen vaccinator, by Dr. Hilliard, 336; bent knee, by J. Morgan, F.R.C.S., 432, 478; improved probe for fistula, by W. Allingham, F.R.C.S., 521

Importance of urinary casts, 389  
Improvements in the operation for recto-vaginal fistula, translated by Dr. Luther, 558  
Incompatibility of pharmacy and medicine, 518  
Incontinence of urine in children, 89  
Indian medical service, 7, 30, 237, 189  
Indian medical notes, 21, 103, 131, 146, 217, 263, 292, 356, 395, 435, 500  
Injurious effect of human milk upon dogs, 163  
Injection of chloral into the veins and cellular tissue, 364  
Infant diet, 332  
Influence of contract doctoring on the expectation of life, 336  
Influence of social and sanitary conditions of religion, by H. W. Acland, M.D., 377  
Inquiries into the causes of goitre, and circumstances under which cretinism is developed, by J. B. Wilson, M.D., 293  
Inter-hospital accommodation, 23  
International Medical Congress, 28  
International Sanitary Conference, 29  
Internal administration of phosphorus, 163

INTRODUCTORY LECTURES.

### MEDICAL PROBLEMS OF THE DAY. (a)

By NATHAN ALLEN, M.D.

[THE first part of the address referred to the early origin of medicine, tracing it to the dawn of the sciences of anatomy, physiology, pathology, and hygiene, the four pillars of medicine. Dr. Allen then spoke on several subjects as follows:—]

*State Medicine.*—This phrase refers to the employment of measures for the promotion of public health and the prevention of disease by means of legislation. It is only about thirty years since any decided steps were taken in this direction, either in Europe or in this country. It is true that for a much longer period there had been legislation with reference to quarantine and the establishment of boards of health, but no decided and active legislative measures had been taken directly for the good of the people at large. In Great Britain much progress has already been made in sanitary reform. The reports of the registrar-general, of royal commissions, of local boards of health, papers read before scientific associations, together with discussions in Parliament, in journals, and books, have attracted very general attention to this subject. Parliament has scarcely held a session for twenty years without having had some discussion, or passed some act referring to health. The principal topics upon which legislation there has taken place are drainage, sewerage, water supplies, removal of nuisances, construction of lodging houses, hours of labour, public baths, epidemic and contagious diseases. In 1872, several of these laws were remodelled, making them more practical; and new acts were passed, providing for the appointment of health officers to see that these laws were more efficiently executed in all parts of the kingdom. So general has been the interest created upon this subject, it was predicted by

the present Prime Minister that the next great political agitation in England would be on sanitary reform.

In this country our own commonwealth has taken the lead in legislation. In 1841 acts were passed establishing throughout the State a uniform registration of births, marriages, and deaths, which has been continued for over thirty years. These reports embody the most valuable documents upon vital statistics that can be found in the country. In 1849 an act was passed providing for a sanitary survey of the State, which brought together many valuable facts and statistics relating to health, especially in several of the leading cities of the commonwealth. In 1869 a State Board of Health was created by our legislature. In each step of this legislation it should be stated, that the project was first started in the Massachusetts Medical Society, memorialising the legislature upon the subject. To the credit of this society it should also be stated, that for thirty years or more it has made repeatedly special efforts for the promotion of public health, either at its business meetings, or by addresses and papers published in its name. But a great work yet remains for the Society to do in this same direction. We should not omit to state that in 1850 two very important acts were passed by the legislature, requiring that physiology and hygiene should be taught in all the public schools of the Commonwealth, and that teachers should be examined in the elementary principles of these sciences; but as the enforcement of those acts was left discretionary with school committees, the results have not been altogether satisfactory.

But the Act creating a State Board of Health is the most important step taken in legislation. This board has now published five reports, which are an honour to the profession and a credit to the Commonwealth. It has a very difficult work to accomplish, and should be sustained by every member of this society. New questions in sanitary science are coming up for consideration, which will require some positive legislation. The pecuniary interests of individuals and of the public are found to be in open conflict with the lives and health of the people. For instance—have individuals or companies a right to poison the air or water, which may destroy the health or the lives of multi-

(a) Part of the annual address before the Massachusetts Medical Society, assembled in Boston June 3rd.

tudes? Shall poisoned or adulterated foods be offered in our markets for sale? How long shall it be permitted to construct and rent tenement houses in such a manner as to breed disease and pestilence? Legislation has always placed great powers in boards of health; but either for the want of sufficient intelligence, or from some political motives, they are frequently very dilatory in enforcing the law. Within a few years we have had several marked illustrations of this character. In 1871 and 1872 the small-pox prevailed as an epidemic in Lowell and Boston, which might easily have been checked in its first stages. The boards of health in both cities shamefully neglected their duty; and, while they for months were contending about minor points, and shuffling for place and power, the epidemic raged with great violence. Public opinion finally compelled the formation of new boards of health, which, by introducing efficient measures, arrested at once the progress of the epidemics. But by this delay more than a thousand lives were sacrificed, a great amount of sickness was caused, and an immense bill of expense incurred. These two cases show the vast importance of having competent and efficient boards of health. Human life and public safety and interests should never be thus jeopardised. As extraordinary powers are conferred by legislation upon such boards, placing in their hands the health and lives of the community, it becomes a matter of the highest moment that they be composed of men thoroughly qualified for the duties of the place. The medical profession should always be here represented by its best men, who, by advice and influence, should take the lead in all measures for preventing or arresting the progress of disease. The voice and influence of the profession, too, should be felt in the halls of legislation, and in the management of our public institutions. Medical knowledge should be brought into requisition in these high places of power and influence to a far greater extent than it has been hitherto. The chief cause of our defective and dependent classes may be found in the violation of physiological laws. The causes of idiocy, blindness, mutism, and insanity, arise obviously from this source; and the causes of pauperism and crime may be traced, more or less, to the violation of physical laws. And the more thoroughly the primary causes of many other evils that afflict society and require legislation are investigated, it will be found that they arise from some violation or perversion of physiological laws. No radical or permanent reform can be reached without going back to the primary sources or causes of the evil. In aiding to accomplish this great work, the medical profession sustain a most intimate and important relation to what may be denominated—

*Public Hygiene.*—This includes not merely prevention of disease, but every agency that renders the growth and organisation of the body more perfect, and its decay less rapid. By reference to the organisation of the Massachusetts Medical Society, it will be seen, that this was one of its principal objects. The very first sentence in its charter reads, "As health is essentially necessary to the happiness of society, and as its preservation or recovery is closely connected with the knowledge of the animal economy, and of the properties and effects of medicines, &c., be it therefore enacted," &c. And then in specifying its objects in another place, it says, "to increase and diffuse medical knowledge." It would seem, therefore, that one of the primary objects in the organisation of this Society was to promote the health of the community, to prevent disease, and diffuse medical knowledge. It is impossible to accomplish this object without making the public generally acquainted with the laws of physiology and hygiene. The objects intended by State medicine cannot effectually be attained without a general understanding of those subjects. The practical application of legislation, and the execution of law in a republic, where especially personal rights and interests are involved, depend upon knowledge as well as a sense of justice. It has been repeatedly demonstrated that the ravages of small-pox, cholera, and yellow fever can be prevented or checked by applying sanitary law; but, in order to do this, the people themselves must be

made acquainted with the means of doing it. They must become participators in the work; otherwise it cannot be accomplished. Without referring to facts and figures on the subject, it may be safely stated, we believe, that full one-third of all the prevalent diseases of the day may be prevented by faithful application of hygienic laws; but the people themselves must first understand these facts. Once there might have been a difference of opinion among the members of the profession about the expediency of diffusing such information, alleging that a bad use was made of it—that a little learning, a smattering of such knowledge, was a dangerous thing. Illustrations of this character are constantly occurring; but if some abuse and pervert this knowledge, all do not—multitudes make a good use of it. The evils are only incidental to a higher good.

Besides, much depends upon the manner in which this information is communicated. The objects and agencies by which this has at times been attempted are of a very questionable character. Almanacs, circulars, advertisements, and immoral publications, have been scattered broadcast, professedly to promote health; but the leading motives and objects were very different. It may be said that such a bountiful supply would not exist if there was not a demand for knowledge of this sort—that the public are bound in some way to obtain it. Accordingly we find in newspapers and periodicals an increasing demand and supply of articles on health; also our journals and books, that are devoted more exclusively to the subject, are constantly multiplying. It is very important, in communicating this information, that a proper direction be given to it, and that it should be tempered with the right spirit and motive. In diffusing a knowledge of hygiene it is not expected that every person will become familiar with the details of physiology, or with all the relations it sustains to the laws of life and health. If the more intelligent and influential members of society obtain this information, they will direct public opinion, and gradually enlighten the masses as to their duties and dangers.

Inasmuch as such knowledge properly applied is calculated to prevent a vast amount of suffering, sickness, and mortality, is it not clearly the duty of the profession and the press to use all suitable means for its diffusion? The more enlightened the community become, generally, upon this subject, the less exposed it will be to imposition and quackery. Instead of blind superstition and credulity, a rational faith will grow up in the study and observance of the laws of health and life. The demand in the use of remedial means will be directed to the best skill and experience which can be found, that grows out of a profound knowledge of physiology and hygiene. Let the principles of science and the exercise of good common sense direct and control in all these matters. For it is in this way, and by this means only, that all kinds of empiricism and quackery, root and branch, can be eradicated. The public have infinitely more at stake in attempting to effect such a reform than the medical profession. The visions of the alchemist in search after the "elixir of life" or the "philosopher's stone" may yet in some measure be realised by the diffusion of hygienic knowledge. For wherever the laws of hygiene have been faithfully observed, it has greatly improved not only individual health, but diminished the amount of sickness as well as of mortality. In certain localities in Great Britain, where these laws have been tested for a series of years, the registration reports show a diminution of mortality of one-third to one-half. Such a result we should naturally expect. The more thoroughly the causes of disease are understood, the more and more are they found traceable to a violation of hygienic laws. If the ravages of cholera, of yellow fever and typhoid may be controlled in a great measure by the observance of such laws, why may not scarlet fever, measles and whooping cough—those scourges of infant life—be prevented, or very much limited? The prevailing sentiment that all children must necessarily have these diseases once, finds no support whatever in the nature of physiology or in the principles of hygiene. The fact is already well-established, that the

spread and violence of scarlet fever, by isolation, cleanliness, and ventilation, are very much modified, and, in some instances, entirely prevented. We believe the time will come when scarlet fever, measles, and whooping-cough, which now destroy multitudes of children, will become, in a measure, things of the past. It is not only the great amount of sickness and mortality occasioned directly by these diseases, but the impaired constitutions and other complaints consequent upon them, that may also be prevented. When the community realise fully that the means of preserving health, especially in early life, are placed in a great measure in its own hands, a far higher estimate will be placed upon the value of human life, and the responsibility for its preservation will be found to depend in a great measure upon human efforts. For this sentiment of responsibility, which harmonises with all great principles of justice and accountability, increases just in proportion as the laws of physical organisation are thus brought out and applied. When disease, instead of being wrapt up, in its origin and progress, in a kind of mystery, can be traced to an intelligible source or cause; when it shall be clearly perceived that sickness and premature mortality are the results of violated law, then will our own interest in the subject be greatly enhanced—then will the responsibility be transferred from a "divine Providence" to human agency.

(To be continued.)

## TWO CASES IN WHICH THE PNEUMATIC ASPIRATOR WAS EMPLOYED SUCCESSFULLY.

By E. W. LEE, M.D., Chicago.

**CASE I.**—G. M., æt. 74 years, called upon me early on the morning of February 5th, complaining of inability to urinate. A few questions elicited evidences of chronic prostatic enlargement, which was confirmed by a digital examination, the gland being of great size, indurated, but quite insensitive, pressure being freely borne without pain.

I at once attempted to empty the bladder by catheterism, but after repeated efforts with various sizes of instruments, was reluctantly obliged to desist. I then resorted to hip-baths, injections per rectum of warm water, with opium, &c., internally. A second and repeated attempts to introduce the catheter at intervals until the afternoon of the 6th were invariably unsuccessful. Up to this time the kidneys were not secreting actively, hence there was no painful distension; but slight symptoms of coma ensuing, it became imperative to at once empty the bladder and promote free action of the kidneys. As I could not introduce the catheter, and puncturing the viscus through the rectum was contra-indicated by age and general condition, I determined to use my pneumatic aspirator, which was done with the most gratifying results. A medium-sized needle of the aspirator being introduced immediately above the pubis, allowed the escape of thirty ounces of turbid and bloody urine. The operation was repeated twice on the 7th, thirty-five and forty-two ounces respectively being discharged, more nearly normal in quality. On the morning of the 8th I succeeded in carrying a No. 8 catheter into the bladder with comparative facility, and on the 9th the patient passed the instrument himself. There was not the slightest untoward symptom from the punctures of the bladder, and the man made a good recovery.

**CASE II.**—I was called on the evening of the 22nd of March to see T. K., æt. 30 years. He informed me that he had suffered for years from hernia, and that hitherto he could readily reduce it, but was now unable to do so. On examination I found a large scrotal hernia, strangulated. The man was in great pain, vomiting freely; skin cold and clammy; pulse fifty beats per minute, and weak; anxious expression of countenance.

I injected half a grain morph. sulph. hypodermically, with marked benefit, the pulse getting firmer and the skin

warm and dry, pain also being removed to a great extent. I now had the patient anæsthetised, and having applied taxis until I became satisfied that it could not succeed, I introduced the finest needle of the aspirator, and drew off seven ounces of rather thick, bloody serum. Withdrawing the instrument I introduced one of larger calibre, which had the effect of liberating a quantity of air. These procedures reduced the volume of the tumour considerably, when, to my great satisfaction, with very little effort, the intestine was returned to the cavity to which it belonged. There was some tympanitis and tenderness of the abdomen for a couple of days, but the man made a good recovery.—*Chicago Medical Journal.*

### EXAMINATION.

LONDON gossip is just now very much concerned with the mode of conducting examinations—so much so, indeed that the interest attaching to the coming election into the Council of the College of Surgeons is made to depend on the changes it may produce in the examinations. The College occupies so large a place among the English corporations that the interest felt in its prosperity is very great, and it is usually popular with all classes. Of late, however, murmurs both loud and deep have been heard in many quarters, and some have turned their backs on its portals, determined never again to approach them. The discontent affects candidates for both diplomas; but the unusual proportion of rejections for the higher distinction has given rise to more comment than the apparently sudden raising of the lower standard.

On the one hand we are told that, at the late Fellowship examinations men were "spun" who were known to be well prepared, and who had been assured by the best teachers that they must pass. On the other hand, it is said that the examiners are determined to keep up the standard of the Fellowship, and that nothing will prevent them from doing their duty.

This resolution is one which all would applaud, and we believe even rejected candidates do not desire a lowering of the standard. It would be a farce to institute an examination for a higher distinction which did not afford some guarantee of wider and more exact information. We therefore look upon the virtuous resolution reported of the examiners as nothing more than an excuse for the events that have brought their method into discussion. Candidates, both successful and unsuccessful, agree that

the late examinations have been very unsatisfactory tests of their attainments, and, after spending hours in hearing a recapitulation of those examinations, and reading the questions, we are much inclined to agree with them.

The examiners used to have a horror of the old-fashioned "grinder;" but really the most recent *vivâ voce* examinations might well have been the result of reminiscences of some of the worst "trituration" processes of a generation since. We have the utmost contempt for mere "catch questions," and consider that an examiner who resorts to them is ignorant of his business. Indeed, were we once more candidates and found ourselves thus interrogated, we should hope to have presence of mind to remonstrate. If some one "up to all the tips" would, while answering everyone, retort upon his examiner, it might awaken the reflection that the world has not stood still while examiners have been climbing to their exalted posts.

Another complaint is heard. It has often been made before, and we in our own time experienced it. It relates to the want of consideration sometimes shown to candidates, who speak of it as impoliteness, and even use much more emphatic words. Assuredly a candidate has a right to expect to be treated as a gentleman. The examiner who forgets this loses his claim to the title.

To evince vexation at gross ignorance is to exceed his duty; but to be overbearing is unpardonable. We have heard most complaints of college manners from candidates for the Membership, but some seeking the Fellowship have also urged this grievance on our notice. We trust the mere mention of it may suffice to prevent cause for any future complaint of the kind.

If we look at the papers we find that the College plan, in spite of many changes, is the same as it was—viz., to form a rapid estimate and pass or pluck upon that. At other institutions—notably at the London University—the opposite plan is adopted of giving the candidate the opportunity of showing what he knows, and of taking time to estimate this. There is something to be said for both methods. For the former it may be alleged that a man who can rapidly state his knowledge of two or three things is probably as well prepared on the major number. For the latter it may be said there is less chance of an ill-informed man passing because he was lucky in his questions, or a much better man being rejected from being taken on his weak point. Obviously the former method is most adapted for *vivâ voce*, and the latter for written examinations; and now the College combines both plans it may be worth while to consider whether it would not be better to give a choice of written questions as at the University. We trust while the standard is maintained every effort will be made to secure that those who reach it shall not be rejected.

With regard to Membership we may say that, practical as it may seem, the exhibition of "pickles," and the demand, "what's that, Sir," and a display of vexation at hesitation, is a sorry substitute for skill in examining. We have known these "pickles" fatal to men well up in practice and in pathology who had done well with their written papers, and that, too, when the said "pickles" required a label to explain what they were to good anatomists and surgeons who did not care much for "preparations." It has often been said to us that the examiners themselves would not have known some preparations could the bottles have been changed.

## OUR PAUPER CHILDREN.

WHAT is to be done with our pauper children in the way of making them useful members of society? is a question often asked, and of considerable national importance—whether it is better to herd the innately viciously-disposed offspring of whores and rogues with the sprinkling of the children of misfortune in pauper schools, or separate and train them in the decent homes of our labouring population, where they will be brought under the humanising influence of home life. In Scotland this question has been happily decided in favour of *boarding out*, as it is termed, and, as we know, with the happiest and best results. In the House of Lords last week the question was asked by Earl De la Warr, who directed the attention of the Government once more to the comparative advantage of the *boarding out* system over that of union schools. Mr. Goschen, in 1870, after considerable pressure had been brought to bear upon him, made an order to enable boards of guardians to place out orphan and deserted children; but these regulations, it appears, only applied to these particular classes of children, and not to those born in the union-house. It is computed that there are upwards of 20,000 of the latter class in England and Wales, and it appears that not more than 2,500 were boarded out. In 47 unions in the year 1873 the system of boarding out children was adopted; the guardians, with very few exceptions, expressed satisfaction at the results, and it might be inferred that it was from the want of encouragement and support that the practice was not more general. Nevertheless, it has been found that the evils arising from the massing together of children, and especially of pauper children, not always the most healthy, were very great; as an instance, the Kingston (Surrey) Union, in the year 1872, sent some of the children to the district schools at Penge, but they reported that the result was most unsatisfactory. They did not find fault with the arrangements at Penge, but they gave as their opinion that it was "the natural sequence of massing together so large a number of children of the pauper class;" and it was further stated that "many of the children who had been sent to the Penge district school healthy and strong returned in a deplorable state to their homes after a few weeks' stay at the school, suffering from ophthalmia and cutaneous diseases. The boarding out system was afterwards tried with success. It had also been recently stated with reference to the large school at Anerley, that the Croydon Board of Guardians had had great difficulties to contend with in consequence of persistent ophthalmia affecting the children. There were many other instances of the evils in a sanitary point of view of bringing together large numbers of children.

The late President of the Local Government Board, Mr. Stansfeld, in 1873, said of the boarding out system:—

"The reports which we have received on the children generally are favourable as to their health, appearance, and management, and exhibit a satisfactory result in this respect of the system of boarding out orphan and deserted pauper children under the immediate supervision of committees who voluntarily undertake the duty."

The noble lord stated with regard to the moral aspect of the question, "it was, unhappily, a certain fact that a union-house education exercised a very injurious influence upon the future moral and social character of the children, and in one instance which he mentioned, out of 80 girls

educated in a union school, scarcely one escaped moral degradation in after life. It could not be doubted that these evils would be greatly mitigated if orphan and deserted children were placed under the better influences of home and domestic life. With reference to the question as affecting the ratepayers, they derive no advantage from having large union or district schools. The subject was recently discussed at the Lancashire Sessions, at Preston, and it appeared that the cost of each child at the Swinton District School, near Manchester, stated to be one of the best of the class, was 6s. 4d. a week, and at the Leeds Schools 7s. 7d., whereas in England the average on the boarding out system is about 5s., and in Scotland, where it was very general, it did not much exceed 3s. 6d. or 4s. In returns made to the Local Government Board, it appears that the average cost of a child in a district school was nearly 10s. a week. Mr. Henley, in a report to the Poor-law Board in the year 1870 on the boarding out system as practised in Scotland, says :—

“Boarded out children certainly acquire a more robust constitution, and apparently greater mental activity, than children reared in an ordinary workhouse, and these two points strike at the very root of pauperism, as the majority who fall upon the rates do so from mental or physical weakness.”

It was time that some steps were taken to ascertain the number of pauper children boarded out in the different unions, and the average cost per week of each pauper child to the ratepayers.

#### THE PUBLIC HEALTH BILL (IRELAND).

SINCE our last issue the Public Health Bill has been reprinted, and amended in some respects; clause 10 which concerns our profession immediately, runs thus as now amended :—

“Every medical officer of a dispensary district shall be a sanitary officer for such district, or for such part thereof as he shall personally be in charge of, with such additional salary as the Local Government Board shall determine or approve; and every sanitary authority, whether urban or rural, shall appoint such other sanitary officers, including a medical superintendent officer of health, when deemed necessary, as the Local Government Board shall in each case direct, with such salaries or additional salaries as the said Board shall determine or approve; and the said Board shall assign to the dispensary medical officers, and to the other sanitary officers, if any, and to the medical superintendent officer of health, if such an officer be appointed for the sanitary district, their respective duties and functions in the discovery or inspection or removal of nuisances, in the supply of pure water, in the making or repairing of sewers and drains, or in generally superintending the execution of the sanitary laws within the district.”

N.B.—Dr. Brady, M.P., has given notice that he will move to omit the words “medical superintendent officer,” and insert, “and in case it shall be deemed necessary to appoint a medical superintendent officer, the Local Government Board shall appoint the same at such salary as may be proper.”

“Every such salary or additional salary so determined or approved shall be payable from such local fund as the Local Government Board shall indicate as properly chargeable therewith, and such part thereof as Parliament shall from time to time determine shall be recouped to such local fund out of moneys to be voted by Parliament; and the Local Government Board shall have the same powers

with regard to the qualification, appointment, duties, salary, and tenure of office of every sanitary officer as they have in the case of the medical officer of a dispensary district.

“11. Inspectors of the Local Government Board may attend any meetings of sanitary authorities during the transaction of business arising under any of the provisions of the Sanitary Acts; and such inspectors shall, for the purposes of any inquiry directed by the said Local Government Board, in relation to witnesses and their examination, the production of papers and accounts, the inspection of places and matters required to be inspected, have for the purposes of the Sanitary Acts or Burial Ground Acts or any of the said Acts similar powers to those which inspectors have under the Poor-law Acts and under the Medical Charities Act for the purposes of those Acts.”

It will be seen that *medical* superintendent is now recognised at the discretion of the Local Government Board; this Board possesses already by the Medical Charities Act the powers of appointing inspectors, so that we may now more clearly understand that the working machinery will be :—

1. Inspectors who by clause 11 are entitled to attend any sanitary meetings, and are to be appointed by the Local Government Board.

2. Medical superintendents who are at present supposed by the wording of the Bill will be elected by the sanitary authorities of the district, whether this be urban, rural, or compound. The above amendment by Dr. Brady proposes to alter this, and has the general support of the profession.

3. Sanitary officer—i.e., the dispensary medical officer—appointed by the guardians as at present, and contingent on his appointment as medical officer.

4. Inspector of nuisances, or some such officer as may seem necessary, to be appointed by the sanitary authorities.

Medical officers of dispensaries will doubtless have increased duties to perform which are incidental, more or less, to their usual medical duties; they therefore must endeavour to have the remuneration awarded on such a sufficiently liberal scale, and the amount of which, as it is in the hands of the Local Government Board to decide on from its acquaintance with the working of the Poor-law Medical Service, we may feel sure will be proportioned with due consideration for such additional services. The Bill proposes at clause 30 compensation in certain cases, as follows :—

“If any officer of any body by this Act constituted the sanitary authority of any district is, by or in pursuance of this Act or of any provisional order made under the authority of this Act, removed from his office or deprived of the whole or part of the emoluments of his office, and is not employed in an office of equal value by such sanitary authority, the Local Government Board may by order award to such officer such compensation as the said Board may think just; and such compensation may be by way of annuity or otherwise, and shall be paid by the authority of the sanitary district in which such officer held his office out of the rates applicable to sanitary purposes within that district.”

This must be acknowledged to be a step in the right direction, as boards of guardians evidence too frequently a grudging spirit towards officers who for years have been in their service, and have performed arduous duties with regularity and attention. If the superannuation for medical services was also apportioned by the Local Government Board we apprehend a more contented spirit would

prevail, and dispensary officers would enter on and discharge their duties with greater energy and confidence were it certified to them that at the end of a long career of active work they would depend for their superannuation allowance not on the caprice of a varying Board of Guardians, but of a Local Government Board, who would not be influenced either by motives of private pique or of ill-judged parsimony. We must hope the time is approaching.

The College of Surgeons and Physicians have, at considerable expense, sent deputations to London to urge the introduction of *medical* superintendents and other improvements in the Bill, and we have already called on our friends and medical brethren throughout the country to bestir themselves, and use what influence they can with energy and consistency. Copies of the Bill have been sent to all members of the Irish Medical Association, which was down for reading on the first opportunity. Friday night last was named for it, but it was not then possible to enter on the discussion; but it will be taken probably this week.

## Notes on Current Topics.

### The Queen on Vivisection.

THE jubilee of the Royal Society for the Prevention of Cruelty to Animals was celebrated last week. Her Majesty the Queen sent a letter expressing horror at the cruelty often inflicted thoughtlessly on animals. The Queen then referred to experiments in pursuit of science, and expressed a trust that the anaesthetics of which man availed himself were constantly employed to prevent suffering from such experiments. This is the rational mode of looking at the recent controversy on vivisection. While we admit largely the claims of really scientific men to carry out experiments designed to advance physiology, we certainly stipulate for the use of anaesthetics, and we believe that most physiologists agree with us. We know that at some of our medical schools a man who neglected to give an anaesthetic as a preliminary to a painful experiment would be regarded as a monster. Medical students, we believe, would not be likely to tolerate such cruelty.

### Nurses for the Sick Poor.

THE public meeting to consider the formation of a national association for training and providing nurses for the sick poor, in reference to which we have already spoken, was duly held last week. The chair was occupied by Sir Rutherford Alcock, K.C.B., who opened the meeting with a brief reference to its object. The first resolution was moved by the Earl of Shaftesbury—viz.: "That with a view to securing better nurses for the sick poor as a sanitary and preventive measure, an association be formed according to the recommendations of the Medical Subcommittee of the Order of St. John for training a body of nurses for that object in London and the provinces, and that a home be established where nurses in training at the London hospitals, or employed as district nurses, may lodge, and where a register of trained nurses requiring

employment may be kept." The Bishop of Rochester seconded the resolution, which was adopted, and other resolutions were passed to carry out the proposal. Now that the plan has been fairly set on foot, we hope that it will prove of great benefit to the sick poor.

### Hospital Sunday Fund.

WE are informed that the Metropolitan Hospital Sunday Fund already exceeds £26,000. This is somewhat in excess of the amount received in a like period last year.

### The Waters of St. Galmier and Couzan.

IN these days, when Acts of Parliament are called into requisition to check adulterations, the public have not unnaturally become inquisitive as to the nature and quality of articles which perforce pass their lips, and the certificate or analysis of some duly constituted authority is now often the only passport for goods to which suspicion did not formerly attach. That this spirit of scepticism is carried too far, we are not disposed to deny, but manufacturers have themselves to thank, and the public are undoubtedly gainers in the long run. Of course, there are articles which it does not pay to adulterate; of these may be mentioned natural mineral waters, the consumption of which increases yearly in enormous proportions, so that the trade in these articles is a very flourishing one in most civilised countries. Our readers are probably aware of the names of the best known sources, and the maladies for which they are usually prescribed. Here are two more, not new by any means, as the celebrated Dr. Laprade wrote of their virtues as far back as 1778; but they are comparatively new to this country, and deserve to be as widely known as many of their rivals. In fact we were led to these remarks on observing the excellent results in some cases of obstinate dyspepsia, and we have, therefore, much pleasure in recommending the waters of St. Galmier and Couzan to the more extensive patronage of the profession. In France we have noticed the water upon almost every table at the hotels at which we stayed, and when we state that in that country no fewer than five millions of bottles of St. Galmier alone are sold annually, its popularity will be readily measured. The importers for this country are the Messrs. Gallais, of Margaret Street, London, W., by whom they are sold at a less price than the ordinary artificial seltzer, soda, and other manufactured waters, which we have found not unfrequently tainted with lead and other impurities of a careless manufacturer. The waters of St. Galmier and Couzan, should be classed with the bicarbonates, soda, potash, magnesia, and iron, being their chief characteristics.

### King's College.

IT is rumoured that at the close of the session Dr. Garrod will retire from the Professorship of Materia Medica, and that Dr. B. Yeo is likely to succeed him. It is not unlikely Dr. Garrod may also resign the Physiciancy to the hospital. The statement that Sir W. Ferguson was about to resign, circulated by a contemporary, was incorrect. Sir William only resigned his seat at the committee, as did also Mr. H. Smith and a dozen lay governors who disapproved the recent decision about nursing.

### The Schoolmaster's Idea of Stupidity.

WHEN will the masters of our middle-class schools become sufficiently intelligent to cease flogging, and endeavour to recognise the differences between disease and stupidity? In the case brought to our notice last week of a little boy dying after a flogging administered in private, the poor little patient was unable to give his version of the extent and severity of the birching administered, and which proved so disastrous. We, however, feel sympathy for all parties concerned—firstly, for the poor little fellow himself, who, like Humphrey in Miss Montgomery's charming story, was "misunderstood," who appeared to be sulky and idle when he was really suffering from an affection of the brain; next for the parents, who will probably always believe, and believe justly, that their affectionate anxiety would have at once divined the real cause of the boy's apparent disinclination to do his lessons, although it escaped the eye of one who stood to him in the colder relation of a preceptor; and, lastly, we may bestow compassion on the schoolmaster himself, who, according to his evidence, does not appear to have acted with any undue severity, but whose chastisement certainly accelerated death. Doubtless he will not easily forget the lesson he has received. In commenting on such cases as these—as in the kindred instances of apoplexy being mistaken for drunkenness—we should be slow to attribute blame in cases where there is no evidence of intentional brutality. We should bear in mind that hundreds of idle boys are flogged, and hundreds of drunken men and women are locked up in police cells every day, whereas the cases where schoolmasters or policemen mistake illness for laziness or intoxication are proportionately rare.

### United Hospitals.

THE sports in connection with the London Hospital Medical Schools came off at Lillie Bridge, on Saturday, under the presidency of Mr. Luther Holden, F.R.C.S. The meeting was a great success, and the prizes fell as under: To King's College, five prizes; St. Bartholomew's, three; Guy's, one; and St. George's, one.

### Indian Medical Service.

WE hear that in consequence of the decease of Dr. Beatson, Surgeon-General Gordon, C.B., will probably go to India.

### The Apothecaries' Company.

THE Bill of the Company to enable them to join in the Conjoint Scheme has passed the House of Commons, and is now before the Lords. A clause declares that nothing is either to deprive or relieve the Company of any right it may now possess to admit women to the examinations for the licence. Does the Company propose to become the licensing body for females?

### General Medical Council.

As Dr. Paget's term of office as President approaches its termination there is a good deal of speculation as to who will succeed him. It is not impossible that an effort will be made to secure his services for another term, and it is very desirable he should consent to act for at least another year.

### London's Lungs.

WE do not intend to dilate upon the open spaces of the great metropolis which might be fairly represented under this title; our object is simply to chronicle the fact that one of the foulest blots in London will to-morrow be removed by the formal gift of Leicester Square to the nation by Mr. Albert Grant, M.P. for Kidderminster. London's lungs will be all the purer for this noble gift, the atmosphere around which has for a long time been polluted with dead cats and dogs and other pestiferous nuisances, making Leicester Square a by-word at home and abroad. What a strange metamorphosis will strike passers-by on the morrow—no huge, ugly hoarding, no blush of shame will arise on their cheeks that the wealthy city of London allows such a scandal to exist in its very midst; but a beautifully laid out garden, with marble statues of Dr. Hunter, Sir Isaac Newton, Hogarth, and Sir Joshua Reynolds to embellish the ground formerly honoured by their residence on it. Could our immortal *confrère* Hunter have witnessed the state of abject degradation to which the square has of late years fallen his mighty spirit would have groaned at the fallen fortunes of a once favoured spot, and blessed the generous donor who has made it to rise again phoenix-like from the ashes of its past greatness. We have no sympathy with those who decry the gift, and attribute it to interested motives. A man has but to make himself great or rich, or to set himself to work out some laudable undertaking, and before starting he may be perfectly certain that all sorts of shafts will be hurled at him, and insinuations such as have during the past week disgraced the hoardings of the metropolis will crop up like weeds to injure his reputation and to lessen the honour that might fully belong to him. Mr. Grant has our entire sympathy and our thanks for so generously handing over to the metropolis another pleasant place to look upon—another lung through which London can respire.

### Exclusion of Physicians from the Commission of the Peace.

WE have read with much astonishment and with some apprehension that we have attached to the Chief Secretary's statement an erroneous interpretation—the report of a reply given by Sir M. H. Beach to a question put to him by Mr. Moore, the Member for Clonmel, in reference to the veto of the nomination of two magistrates by Lord Lismore by the Lords Commissioners, who are now temporarily exercising the functions of the Lord Chancellor in Ireland. Lord Lismore had appointed to the Commission of the Peace a medical gentleman of repute in his county, and Sir M. H. Beach is reported to have stated that the appointment was cancelled because the Government does not consider a physician in practice to be a fit person to be entrusted with the Commission of the Peace. Having regard to the fact that for a long series of years practising physicians have been approved for the office of J.P., and have discharged their duties without the slightest suggestion of impropriety, and as everyone is aware that the Commission is every week granted to petty shopkeepers and persons infinitely inferior in social and educational status to the practising physician, we are

entirely unable to comprehend the declaration of opinion of the Chief Secretary either as a statement of policy or as an authoritative insult to the medical profession. We believe that if the House of Commons were consulted it would be speedily ascertained that the exclusion of medical men from the smallest local official dignity is not desired or approved by Parliament, and we trust that the Irish Medical Association will lose no time in eliciting from the Chief Secretary, through some of the Irish representatives, an explanation of this very extraordinary confession of faith.

THE Fellows of the Royal College of Physicians of London had a dinner last week, which was well attended.

MR. JABEZ HOGG has been elected a Corresponding Fellow of the Philadelphia Academy of Sciences.

DR. J. MILNER FOTHERGILL is a candidate for the vacant Chair of Materia Medica and Therapeutics at King's College, London.

THE additions to the Hunterian Museum for the present year are now on view, and will remain so until after the election of councillors.

AN infant nursery and mission was opened in Wellclose Square last week by the Duke and Duchess of Edinburgh. The Duchess also opened a *crèche* at the East End.

THE session of the General Medical Council is to open July 10th, in the building formerly occupied by the Royal College of Chemistry.

DR. JULIUS POLLOCK has been appointed Lecturer on the Principles and Practice of Medicine, and Dr. Silver Lecturer on Clinical Medicine, at the Charing Cross Hospital Medical School.

DR. J. BURDON SANDERSON, F.R.S., has been appointed Jodrell Professor of Human Physiology (including practical physiology and histology) in University College, London, vice Dr. Sharpey, who has resigned the Chair of Anatomy and Physiology.

THE Earl of Aberdeen presided at a meeting of the City of London Orthopaedic Hospital on Wednesday last. 23,501 cripples, chiefly children, have been treated at this institution since its opening. An appeal was made for funds, of which it seems much in need.

AN out-door fête was held in the gardens of the Home for Incurables on Thursday last, for the purpose of assisting the work of this charity. Unfortunately, the weather was so unpropitious that few went, and those who braved the downpour contented themselves with an inspection of the wards.

THE Medical Council will assemble on the 10th of July, and the meeting will probably be a long one. There will, of course, be not question of a Medical Bill,

but Conjoint Examination Schemes will probably be the subject of lengthened discussion, and the position of the Scotch and Irish corporations will be all the worse in the matter because the English licensing bodies have demonstrated the practicability of unity in examination. Of course the Scotch representatives and Sir Dominic Corrigan will reproduce their arguments against reform of curriculum and examination, but they will probably not succeed in preventing the Council from reiterating their demand for a further effort at conjunction by the Scotch and Irish bodies. We believe that the reports of the visitors of examinations which are about to be presented to the Council are unwontedly forcible, and that they will probably give rise to a great deal of criticism upon the tests of proficiency proposed by some of the colleges.

The Irish Apothecaries' Hall, and the anomalous position which it occupies as a medical licensing body, will also probably be the subject of debate, and Dr. Leet, the representative of the Company, may be obliged to listen to some wholesome truths.

THE annual Harveian Oration, at the Royal College of Physicians of London, was delivered on Saturday afternoon by Dr. West, F.R.C.P., before Sir George Burrows, the President, and a large body of the profession.

THE Dublin corporation decided on Saturday to postpone the consideration of the main drainage scheme until they shall have fixed, in accordance with the Duke of Abercorn's suggestion, on some plan for the immediate purification of the Liffey.

DR. TOLOZAN, Physician to the Shah of Persia, has been elected a corresponding Member of the French Academy in the section of Medicine and Surgery, and M. Studer, of Berne, in that of Geology. The latter is a veteran of 79 years.

IN the House of Commons on Friday the Chancellor of the Exchequer, in reply to Mr. Ellice as to whether the Government had considered and come to any decision relative to the question of extending to pauper lunatics confined in licensed wards of poor-houses, or boarded out under authority from the Board of Lunacy in Scotland, the benefit of the allowance proposed in his statement upon the Budget to be given in respect of pauper lunatics confined in asylums, said that some of the regulations made in Scotland seemed to present a case for fuller consideration, and he would hold communication with the authorities in Scotland before coming to a final conclusion.

IN the House of Commons on Friday the Government was asked to interfere with the adulteration of Irish whisky with an inferior and injurious spirit from Scotland while the former was in bond. The Chancellor of the Exchequer replied that it was impossible to prevent such mixing; all the Government could do was to see that the spirit left the Stores branded with its proper mark as to what it really was; after this was done the public and manufacturers must look after their own interests.

### Cookery.

WE were pleased to observe that Sir Charles Reed, the Chairman of the School Board for London, announced at a late meeting of that body that a letter had been addressed to him by Mrs. Baines, stating that she was prepared to hand over to the Board the sum of 100 guineas, to be devoted to the offering of prizes for essays or manuals on cookery and household work suitable for the use of Board teaching. The letter was referred to the School Management Committee. It was subsequently announced that the offer had been accepted.

Sickness is often aggravated—nay, death may be caused—by the ignorance of those who prepare the food for invalids. This ignorance is fostered by wrong teaching and practice. Practical lessons in cookery can only be useful to illustrate the theory of the subject; the “why and because” of the art should be known, and can be reduced to very simple lessons. The present race of cooks are bad cooks, because they do everything mechanically, by imitation, without any real knowledge of the science of cooking. Mrs. Baines deserves the hearty thanks of all for her gift.

### The Heart in Poisoning by Arsenic.

ECCHYMOSIS of the left ventricle of the heart, or, as otherwise designated, sub-endocardial ecchymosis, is regarded by some as pathognomonic of poisoning by arsenic. Since Dr. Bonavia called attention to this livid and bruised appearance in 1866 several Indian medical officers have recorded analogous cases; these have from time to time appeared in the *Indian Medical Gazette* (vol. i., pp. 252, 302, vol. ii., pp. 120, 75, 84, vol. viii., p. 64), and in the new number of that journal we find an account of the post-mortem examination of the bodies of six individuals who died from poisoning by arsenic, recorded with care by Assistant-Apothecary Mr. Alfred Wright, of the Mysore Commission.

On analysis only four of the six presented this condition in confirmation of Dr. Bonavia's observations.

Surgeon E. O. Tandy described, in March, 1873, in the same journal, a case in which “the heart was full of coagulated blood, natural in size and appearance, with the exception of the left ventricle, the interior of which presented an appearance I had never seen before; there was no sign of inflammation, but in the muscular structure of the ventricle and in the columnæ carniæ there were extravasations of bluish blood resembling recent bruises.”

In 1829 attention was drawn to the state of the heart, particularly the left cavities, for Christison wrote: “It has been stated that the inner surface of the heart has been found red from inflammation. In a case examined judicially at Paris by Orfila, the left cavities of the heart were of a mottled red hue, and in the ventricle were seen many small crimson specks which penetrated into the muscular part of the parietes. Orfila adds that he had previously seen the same appearances in animals (‘Archives Générales,’ i., 147). These observations are not quite satisfactory.

“There is no evidence that the observer drew the distinction between the redness of inflammation and that produced by the dyeing of the membrane with the blood after death. The subject was lately brought before the Royal

Academy of Paris by M. Godard, who had also observed the appearance in question in a person killed by arsenic, and who dwelt strongly on it as characteristic of this species of poisoning. It was distinctly proved, however, by many members present, that the appearance arises from many other causes.”

In respect to the preceding observations made by MM. Orfila and Godard, Mr. Wright says—“What then is the dyeing here spoken of? May it not have been the real pathognomonic condition *sub-endocardial ecchymosis* of Dr. Bonavia, but, from the observations advanced being novel and unsupported either from want of opportunities or special facts by other observers, was not maintained,” and he thinks that Dr. Bonavia has clearly shown and placed beyond all doubt that this appearance is characteristic of poisoning by arsenic.

IN the House of Commons on Thursday, in reply to Mr. Stacpoole, Mr. Gathorne Hardy said that an order on the subject of the exchange of army medical officers was issued in March, 1843. Since that time exchanges had not been encouraged, although there had been exchanges under the existing system.

## STUDENTS' COLUMN.

### LECTURES ON HUMAN ANATOMY.

By WALTER RIVINGTON, M.S. Lond., F.R.C.S. Eng.,  
Surgeon to the London Hospital and Lecturer on Anatomy at the  
London Hospital Medical College.

#### LECTURE X.

(Continued from page 536.)

*Meaning of the term Thorax—Composition of the Thorax—Modifications of the Thorax among the Classes of Vertebrates—Description of the Sternum—Its Peculiarities of Shape and Structure—The Ribs—Classification—Anatomical Description and Movements—Differential Characters of the Ribs—Special Features of the 1st Rib—The Costal Cartilages—Specimens showing 8 Ribs joining the Sternum—Structure of the Costal Cartilages—Meaning of the term Rib.*

GENTLEMEN,—The Greek word *θώραξ* signified a breastplate, cuirass, or corselet, and was subsequently applied to the parts covered by the breast-plate, or the whole forepart of the body, from the neck to the middle, containing the liver. (a) Still later the term was restricted in medical writings to the breast proper, or chest. As it is now used it means the bony and cartilaginous framework or cage circumscribing the cavity of the chest, and forming part of the boundary of the abdomen.

The osseous walls of the Thorax are composed of thirty-seven bones. In front is the Sternum, or Breast-Bone, behind are the twelve Dorsal Vertebrae, at the sides the twelve pairs of Ribs and their appended Cartilages. The osseo-cartilaginous case thus formed has the shape of a truncated cone with the larger end downwards. It is slightly flattened from before backwards, and open above and below. In the well-built adult its transverse diameter exceeds its antero-posterior, for the purpose of preventing the spinal column from being overloaded in front. This is an obvious adaptation to that erect attitude which is shared by man with the penguin and the kangaroo. A complete Thorax is not to be found in all vertebrate animals. It exists in beasts and birds without exception. In fishes, amphibia, and reptiles, the Thorax is incomplete. Frogs and toads have no ribs; their breathing out of water is a kind of swallowing. They take air into

(a) Liddell and Scott's Greek Lexicon.

their mouths, close the throat and nostrils, and force the air into the lungs. The absence of ribs allows them to compress the body by muscular action and expel the air. This power of compression also enables them to sink in water, and spend the winter in their favourite subaqueous mud. Were it not for this the animals would remain on the surface of the water, "as when cruel boys blow them up with a straw." Serpents have no Sternum, all their Ribs are false Ribs, and are modified for locomotion. With the ends of the Ribs are connected horny plates, and it is by the successive application of the edges of these plates to the ground that they glide noiselessly along. Fishes have few or many Ribs, but are destitute of a Sternum. In Man and in the Mammalia generally, the lower opening of the Thorax is closed by an arched muscular partition called the Diaphragm, which divides the cavity into two parts, an upper part, or Chest, which contains and protects the Heart and Lungs, and a lower part, forming a portion of the Abdomen, and giving shelter and support to some of the organs of digestion, notably the Stomach, Liver, and Spleen. Had the Thorax been intended merely as a protecting structure, this purpose would have been better fulfilled by its being formed as the Pelvis is formed, of strong bones knit almost immovably together, or we might have been clad like the tortoise, in an impenetrable case, inseparably joined to the Ribs, Sternum, and Vertebrae, with leave and licence to retract our heads and necks and feet, and to emerge, as occasion might require, in the easy course of a life of some 200 years. (a) Even as it is, there would appear to be a good deal of the nature of the tortoise in human organisation. Pope tells us :

But the brevity of human life, gentlemen, must be compensated for by activity, and an active mode of life requires activity in the breathing function, and activity in the breathing function requires that the Thorax should be constantly altering its dimensions, and to allow this alteration in its dimensions it is composed of many arched and elastic segments united by movable joints with the vertebral and sternal columns. "The Thorax" says Schellhammer, "forms a kind of bellows such as never have been nor probably will be made by any artificer." (b) The perfection of this instrument can only be understood by a thorough mastery of the dry details of its component parts—*Nil sine labore Deus dedit mortalibus*.

The Sternum, or Breast-bone, is a long flat bone, composed of a series of segments, from which circumstance it is sometimes termed the *Sternal Column*. Like the flat bones in general, it is constructed of two layers of firm compact bone enclosing cancellous tissue. Sloping from above downwards and forwards, and slightly arched in front, it occupies a central position in the anterior wall of the Chest, protecting the Heart and great Blood-vessels which lie behind it, supporting superiorly the Collar-bones, or Clavicles, and receiving on each side the Cartilages of the true Vertebro-sternal ribs.

The term Sternum is derived from the Greek *στένον*, signifying the Breast, or Chest. The bone itself was likened by the fathers of anatomy to a small Roman sword. The upper part of the Sternum represents the *Handle*, or *Manubrium* (*Manus*, a hand), the middle corresponds to the *Blade*, and is called the *Gladiolus* (diminutive of *Gladius*, a sword), and the lower part, which is the point of the sword, is called the *Ensiform*, or *Xiphoid Cartilage*, or Appendage. *Ensiform* is derived from the Latin *Ensis*, a sword, and *Forma*, likeness, and *Xiphoid* from the Greek *ξίφος*, a sword, and *ειδος*, likeness. Both the Latin *Ensis* and the Greek *Xiphos* were straight two-edged swords. The *Manubrium*, in scientific phraseology, is termed the *Pre-Sternum* (Fore-Sternum), the *Gladiolus* the *Meso-Sternum* (Mid-Sternum), and the *Ensiform Cartilage* the *Xiphi-Sternum*.

(a) "The great longevity of these creatures seems to be one of the most remarkable circumstances in their history. One is recorded as living at Peterborough whose age must have been about 120 years. Bishop Marsh's predecessor in the see of Peterborough had remembered it about sixty years, and could recognise no visible change. He was the seventh bishop who had worn the mitre during its sojourn there."—Patterson's "Zoology for Schools," p. 305. Pennant says that a tortoise introduced into Lambeth Palace, in 1633, lived till the year 1753, the time of Archbishop Herring, and might have lived much longer if it had not been accidentally killed by the negligence of the gardener.

"Most souls, 'tis true, but peep out once an age,  
Dull sullen prisoners in the body's cage;  
Dim lights of life that burn a length of years,  
Useless, unseen, as lamps in sepulchres;  
Like Eastern kings a lazy state they keep,  
And close confined to their own palace sleep."

*Elegy to the Memory of an Unfortunate Lady.*

(b) Paley's Natural Theology.

In length the Sternum of the adult male measures from 7 in. to more than 10 in., the Manubrium contributing 1½ in. to 2½ in., the Gladiolus 3 in. to 5 in., and the Ensiform Cartilage 1 in. to 3 in. (a) In width it varies at different points

(a) The following are my measurements of individual specimens coming under my notice :—

and in different specimens. It is widest in the Manubrium between the Cartilages of the 1st pair of Ribs, and then narrows to the 2nd pair. Below the 3rd pair of Ribs it begins again to widen to the 5th pair, and then narrows again to the Ensiform Cartilage, which is usually narrower than the rest of the bone. In some specimens the Gladiolus is tolerably uniform in width throughout, and presents no enlargement at the lower end. The dimensions in all directions are less in the female. The Sternum is developed from a single and continuous piece of Cartilage in 6 different bony segments. In position the Manubrium is the 1st, and the Ensiform Cartilage the 6th piece. The Gladiolus is composed of 4 pieces. These 6 segments remain separate from one another for many years. The 2 lower pieces of the Gladiolus are the first to join, but the whole Gladiolus is not complete till about the age of 40. The Manubrium and Ensiform Cartilage may both be distinct from the Gladiolus in very old age, or one or both may be joined. I am unable positively to say which is joined first, for we have about an equal number of specimens showing on the one hand the Manubrium and Gladiolus united, and the Ensiform Cartilage distinct, and on the other the Gladiolus and Ensiform Cartilage united and the Manubrium distinct. There are several showing the three pieces united, and a great many more which maceration has separated into the Manubrium, Gladiolus, and Ensiform Appendix (a). The Ensiform Cartilage generally ossifies imperfectly, its extremity continuing cartilaginous throughout life.

The Sternum may be described as a whole, or the three pieces may be taken separately. Adopting the former, but perhaps less natural method, we observe that it presents two surfaces, anterior and posterior, two extremities, and two lateral borders.

(a) Ossification sometimes takes place in the Cartilage joining the Manubrium and the Gladiolus at an early age. I have seen it converted into bone at 34 and 36 years of age. The Cartilage joining the Gladiolus and Ensiform Appendix is also liable to early ossification. In both the specimens alluded to above the Ensiform Cartilage and Gladiolus were united by bone. I have also seen the Ensiform Cartilage joined by bone to the Gladiolus when the Manubrium and Gladiolus were distinct from each other. This occurs in two separate orders of specimens—first, in all that class of Sterna in which a gliding joint is found between the Manubrium and the Gladiolus, for in this class I believe that ossification never takes place at the upper sternal joint; secondly, in some Sterna in which an amphiarthrodial joint exists between the Manubrium and Gladiolus. Thus, in a male of 30 the Manubrium and Gladiolus were united by Cartilage, but the Ensiform Appendix and Gladiolus were united by bone. In a male of 44, the Cartilage joining the 3 upper segments was nearly ossified, and the Cartilage joining the two lower segments was completely ossified. Again, in males of 53, 56, and 73, and in females of 41 and 56, I found the upper Cartilage entire, but the lower ossified. On the other hand, I have not noticed in any fresh specimen the Manubrium joined to the Gladiolus by bone, whilst the Ensiform Appendix was united only by cartilage. Hence, I think we may conclude that the Ensiform Cartilage is generally the first to unite by bone to the Gladiolus. That it does not always do so is shown by those dried specimens to which I have alluded above, in which the Manubrium and Gladiolus are united, but the Ensiform Cartilage is distinct.

The anterior surface is either flat or convex from above downwards. In some specimens the bone will lie evenly, or nearly so, on its posterior surface on the table, whilst at others it forms an arch, resting on its two extremities. I believe that the female Sternum is generally less arched than the male. The highest point of the arch varies between a few lines and as much as an inch or more, and is situated at or near the junction of the Manubrium with the Gladiolus. On the anterior surface we notice the narrowed junction of the Manubrium with the Gladiolus, and five transverse lines or indications of the points of union of the several segments. It is by no means uncommon to find the junction of the Manubrium and Gladiolus marked by an elevated ridge, and such a ridge may exist between the third Costal Cartilages, especially when the bone is unusually curved. Muscular impressions may be observed in some specimens. The Posterior Surface is concave, smoother than the anterior, and showing less distinctly the transverse lines alluded to. The Superior Extremity or Border is thick, and has a notch in the centre, which, being placed between the Clavicles, is termed the Inter-clavicular Notch. It allows more room for the Trachea, or Air-Tube. Flanking the notch on each side is a concave cup-like surface, which looks upwards, backwards, and outwards, and articulates with the sternal or inner end of the Clavicle. The Inferior Extremity will be presently noticed.

The Lateral Borders present the facets or depressions for the Costal Cartilages, and between them the intervals which form the anterior ends of the Intercostal Spaces. Beginning from above, we observe below the clavicular facet a depression for the 1st Rib—followed by a concave border which slopes downwards and inwards to the cup-shaped depression for the 2nd Rib formed by a demifacet on the lower angle of the Manubrium and a demifacet on the Gladiolus. Then follow the cups on the Gladiolus for the 3rd, 4th, 5th, and 6th Costal Cartilages, separated by intervals diminishing gradually in depth. The 5th, 6th, and 7th depressions are very close together, the 7th being formed partly by the Gladiolus and partly by the Ensiform Cartilage. The prevailing shape of these cavities is similar to that of notches cut out of a stick. It is extremely interesting to observe that the mode in which the Ribs join the Sternum corresponds very closely with their manner of articulation with the Vertebrae. Thus, the 1st Rib, which is jointed to only one, the first Dorsal Vertebra behind, is united in front by means of its cartilage to a single piece of the Sternum, the Manubrium. The 2nd, 3rd, 4th, 5th, 6th, and 7th Costal Cartilages articulate with two contiguous segments of the Sternum just as the heads of the Ribs articulate with two Vertebrae; the 2nd with the Manubrium and the 1st piece of the Gladiolus; the 3rd with the 1st and 2nd pieces of the Gladiolus; the 4th with the 2nd and 3rd; the 5th with the 3rd and 4th, and the 7th with the 4th piece of the Gladiolus and the 6th of the Sternum or Ensiform Cartilage. The 6th is the "exception which proves the rule." It joins the middle of the 4th piece of the Gladiolus. Possibly Nature intended to have another segment to the Gladiolus, but failed satisfactorily to accomplish her purpose. At the lower part of the Gladiolus she waxes a little weak occasionally in her developmental efforts, and leaves an aperture persistent throughout life. Here is a specimen of this imperfection: a small round hole is left between the cups for the fifth pair Ribs. Here is another in which the hole is between the sixth Ribs.

A deficiency of this nature may extend throughout the Sternum, which is then divided into two parts by a median fissure. The case of M. Groux is well known. He exhibited himself in London some years ago. His Sternum was cleft from top to bottom in the middle line. He could narrow the fissure by bringing his hands together, or enlarge it till it was between two and three inches wide. It was covered by skin and fascia, and gave him little inconvenience. When the soft parts are also deficient and the thoracic cavity is open, exposing the Heart, the deformity is exceedingly severe; such a condition is called Ectopia Cordis. Instances of deficient formation with Prolapse of the Heart have been described. "In this prolapse the heart may protrude either alone or in connection with other thoracic and abdominal viscera at the neck, or in the absence of the breast-bone and through congenital holes and clefts of that bone, either higher or lower upon the breast, or close under the point of the breast-bone and at the top of the belly." (a)

The Ensiform Cartilage is very variously shaped, often unsymmetrical, and often distorted. It averages, it is said, about

an inch in length; but several specimens before me are more than two inches long. In this specimen it is broad and truncated below. In this specimen it is three quarters of an inch wide above for the distance of an inch, and ends in a narrow pointed process an inch in length. In this specimen it ends in two prongs nearly equal and parallel; and in this in two prongs of unequal size, the longer prong continuing a nearly straight course downwards, and the other being deflected to one side. In this specimen it tapers gradually from above downwards.

It is often perforated by a hole, either large or small, and rarely by two. The Ensiform Cartilage is not very readily felt in the living subject. It is sometimes depressed below the level of the anterior surface of the Sternum, or the cartilages of the Ribs project in front of it, or it is embedded in the soft structures connected to it. (x)

It affords some little protection to the Stomach, and attaches the Muscles of the Abdomen, its own ligaments, and an important band of white fibrous tissue which extends from its extremity in the middle line of the Abdomen to the Pubes. This long central ligament is called the *Linea Alba*, or *White Line*, from its structure and appearance, and may be regarded as the continuation or abdominal representative of the Sternum—a view corroborated by the fact that in some subjects the Ensiform Cartilage may extend down to the navel. In a monster it has been seen to reach the Symphysis Pubis, with which it formed a cartilaginous union. The distortion of the appendage often observed may be produced in certain occupations by pressure applied to the "pit of the stomach."

## Correspondence.

### THE EXPECTED MEDICAL BARONETCY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the last few numbers of your excellent journal I have seen letters in which the writers express a hope that the eminent Dublin physician, Dr. Wm. Stokes, should be made a baronet. I beg to say that I most cordially agree with all that is said in those letters in favour of Dr. Stokes receiving this distinction; and in giving this opinion I believe I am not only expressing the feeling of the members of this profession everywhere, but of the general public. The medical teaching in Dublin has always been considered of a high order; and for more than the last thirty years Dr. Stokes has been one of the most learned professors in that city.

He has also been a distinguished hospital physician and a well-known author. It has been remarked that the members of the medical profession in Ireland have not received the same distinction as their brethren in England. It is now, however, confidently hoped that they will not have much longer to complain, and that our present Government will make some recognition of the public claim and worth of Dr. W. Stokes.

I am, Sir, your obedient servant,

ABRAHAM KIDD, M.D., M.R.I.A., L.K.Q.C.P.I.

Ballymena, June 25th, 1874.

### PHARMACY IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I enclose you the copy of a circular which has been sent to every Irish Member of Parliament. In addition to the observations contained in it, will you permit me to make the following remarks:—

When Dr. Leet stated some time ago, "that there were, to his knowledge, from twenty-eight to thirty of the most important towns of Ireland, with populations varying from 10,000 to 50,000, wherein there was no apothecary or competent person qualified to compound medicine," he evidently erred egregiously, since there are not more than sixteen towns in all Ireland (according to the Census of 1861) whose population exceeds 10,000, and in every one of these a sufficient number of apothecaries exist for all requirements, so that no inconvenience can result.

(a) Of 34 Ensiform Cartilages, 10 were single and perforated, 13 single and without perforation, 10 bifurcated either equally or unequally, and 1 tripartite.

Ireland at present has no need for Pharmacy Acts such as those passed for England in the years 1852 and 1868, for, whereas in the latter country there was urgent necessity to regulate the practice of pharmacy, since any uneducated person might open a shop to compound and dispense medicines before those Bills were passed, and the Pharmaceutical Society of Great Britain was formed to raise the standard of pharmaceutical education, in this country the standard does not require to be raised, but only modified for the future by the omission of purely medical and surgical subjects from the curriculum prescribed.

The fifteenth clause of the proposed Pharmacy Bill of the Apothecaries' Hall is most objectionable. There is no reason whatever why a druggist in Ireland should not pass through exactly the same ordeal as any other candidate for a pharmaceutical licence. There is no such dearth of competent dispensers throughout the country as to demand the admission of such an imperfectly educated class.

Furthermore, druggists in Ireland labour under no disability, seeing that they have never been legally entitled to dispense medicines, nor have they entered into business with such an intention, unlike the "chemists and druggists" admitted by the English Pharmacy Acts of 1852 and 1868.

I trust these considerations will convince you that our opposition is not of a vexatious nature, and that we seek only what is equitable for the public as well as for ourselves.

Yours faithfully,

Trinity Street, Belfast,  
24th June, 1874.

REUBEN BOLTON.

### PHARMACY IN IRELAND.

May, 1874.

SIR,—As it is intended to introduce into Parliament during the present session one or more bills, to change the law relating to pharmacy in Ireland, we have been directed to request earnestly your careful consideration of the following statements by the Association of Licentiate Apothecaries of Ireland, whose prospects would be vitally affected by the proposed alterations.

By virtue of the Act of Incorporation of the Apothecaries' Hall of Ireland, dated in the year 1791, its licentiates "are the only persons in Ireland who can legally keep a shop for the compounding and dispensing of medicines, and the only practitioners in Ireland who can recover for medicines furnished on the prescriptions of other medical men."

In order to secure the foregoing privileges, it has been necessary for nearly the last forty years that every candidate should be engaged for at least three years at practical pharmacy, that he should spend four years at professional study, and pass examinations sufficient to qualify for a licence in medicine. The diploma then granted is a legally recognised medical qualification throughout the Queen's dominions, and entitles the holder to practise both pharmacy and medicine; but every Irish apothecary must undergo this protracted and expensive course of instruction even to practise pharmacy only, to which a large number of them confine their attention, and are, consequently, entirely dependent on compounding and dispensing medicines for subsistence. It is not contended that the law should still continue thus; but the simple fact is, that the present licentiates have found it so, and have been compelled to conform to it.

To permit any less educated class of pharmacists to attain to the same legal rights (a result sought by the framers of the proposed pharmacy bills) would be virtually to disestablish and disendow the existing Irish apothecaries.

In any legislation on the subject the licentiate apothecaries seek—

1. *Recognition of their vested rights, and compensation from the State for the unnecessary outlay of time, labour, and money to acquire their qualifications in the past, and injury to their interests in the future, by the admission of a lower grade of pharmacists to the same privileges as dispensers of medicine.* A precedent for this exists in the case of the Irish proctors, who were granted compensation when their office was abolished.

2. *The foregoing being conceded, they suggest that the Apothecaries' Hall in Ireland for the future should grant but one licence, and that in pharmacy only, to obtain which the candidate should not be required to attend lectures upon, or be examined in, such subjects as anatomy and physiology, surgery, medicine, or midwifery—which are quite superfluous; but that the standard in the subjects essential to a sound*

pharmaceutical education (such as chemistry, botany, materia medica, pharmacy, &c.) should be as high as possible.

For the public benefit, as well as in ordinary justice to themselves, therefore the members of the Association of Licentiate Apothecaries of Ireland beg, that when either of the proposed Pharmacy Acts shall be introduced into Parliament, you will kindly assist them by your vote and influence to effect these objects, if necessary, by the reference of the entire question to a Select Committee of the House of Commons.

We have the honour to be, Sir,

Your very obedient servants

(Signed on behalf of the Association of Licentiate Apothecaries of Ireland),

## ESTIMATION OF TOTAL NITROGEN IN UREA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am sure you will excuse me for again trespassing on the space allotted to correspondents in your very valuable journal, but as Professor Reynolds has thought fit to imagine I overlooked his experience in organic chemical analysis, allow me to say that I had no idea of provoking a controversy on chemical subjects, but that I had at least a *twofold* reason for noticing his paper on the "Estimation of the Nitrogenous contents of the Urine"—firstly, a desire to save him the trouble of conducting a series of experiments which might be more easily determined; and, secondly, to uphold the fair fame of my own countryman, Dr. Davy, for I cannot imagine a more simple and beautiful mode of determining the amount of nitrogen in the urine than that proposed by him.

As to the late Baron Liebig's process for estimating the amount of urea in the urine, it would indeed be the efforts of a pigmy intellect to detract from his great genius, as neither praise nor censure can affect the memory of that colossus of modern chemistry, which will be a beacon for the light of future generations in both organic and inorganic chemistry; but, as I recollect when a lad attending a lecture on the atomic theory, delivered at the Royal Dublin Society, by the late Professor Higgins, in which he waxed very warm, earnestly contending that the late Dr. Dalton, of Manchester, had filched all his ideas on that beautiful theory (in making which complaint I now believe he was quite justified, having read Dr. Higgins's work on that subject, which I have in my possession), in a similar manner I thought Professor Reynolds had ignored Dr. Davy's mode of analysis for the determination of nitrogen in the urine.

I shall now address myself particularly to Professor Reynolds's remarks, which I think are deserving attention. As to his first—viz., that I ignored his plan for fixing the ammonia by sulphuric acid, it appears to me to be quite irrelevant, as the soda-lime process for the determination of nitrogen, which he employs in the first stage, has been shown by Leegan and Novak to be quite inaccurate for the correct estimation of nitrogen in different nitrogenous compounds of animal origin, a statement which Professor Reynolds has completely passed over without comment. As to his second remark, alleging certain defects in Dr. Davy's test, I may observe he goes on mere assertion without proof.

But to return to the method proposed by Professor Reynolds

(independent of all other objections), I cannot conceive anything more fallacious than the depth of the brown tint produced by Nessler's test being taken as the means of estimating the amount of ammonia furnished in the first stage of his process, as everyone knows that the observance of the shade or depth of colour developed in any chemical reaction must be a most unreliable method of quantitative analysis, and could only give results on which any dependence might be placed, when obtained by those in the constant practice of such colour examinations; but granting that Professor Reynolds's method, when carefully executed, was free from all sources of error, the amount of time and the manipulative skill required for its performance appears to me to limit its use altogether to the professional chemist, or to one skilled in chemical analysis; but as most of our practising physicians cannot afford the one, and do not possess the other, such a process is, to them, practically useless. Such objections, however, cannot be urged against Dr. Davy's simple and expeditious method, and as I am thoroughly satisfied with it I shall continue to employ it in my analyses till I am convinced that it has been superseded by a better one, and I leave to others the discussion of the comparative merits or demerits of the different processes which have been proposed for the determination of the nitrogen in the urinary secretion, as I have no leisure or inclination to carry on such a controversy.

Thanking you, Mr. Editor, for allowing me space in your overcrowded columns,

I am, Sir, your obedient servant,

R. AUSTIN, M.D.,

5 Cullenswood Terrace, Ranelagh. Medical Analyst.

## THE PATHOLOGY OF THE ARTERIES IN BRIGHT'S DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the last number of your journal there is a lecture on Bright's disease, by Dr. Campbell Black, which contains some inaccuracies as to the views of Dr. George Johnson on the subject of the changes produced in the vascular system by chronic Bright's disease.

Dr. Johnson's views are so important, and light up so clearly the condition of the vascular system in this renal change, that it is desirable that the matter be put fairly before the public. The lecturer first says: "Dr. George Johnson claims to have discovered thickening of the arteries in this affection in 1850, but Rayer, Bright, and succeeding writers described the same condition long antecedent to the period in question." Neither in my perusal of Dr. Johnson's valuable writings nor in my personal intercourse with him have I ever known such claim preferred by Dr. Johnson, and I do not believe it exists. What Dr. Johnson does claim, and very properly too, is that he was the first to point out that the muscular walls of the arterioles are hypertrophied in chronic Bright's disease, a very different matter from the vague term "thickening."

The next inaccuracy is a curious mis-statement. It runs so: "Dr. Johnson has ascribed the hypertrophy of the left ventricle to obstruction to the renal circulation, . . . but the explanation seems to me to carry its own refutation on the face of it." In reality, this is an old view of Prof. Traube's, of Berlin, published by him in 1855 in a very interesting paper on the connection (Zusammenhang) of kidney disease and heart disease. At that time Traube held the view that the obstruction offered to the circulation in the kidney by its shrinking (Nieren schrumpfung) was the cause of the heightened arterial tension and the hypertrophy of the ventricle found so commonly under these circumstances. Traube's more recent views hold this renal obstruction as but a small factor in the production of the increased arterial tension. He now holds that the obstruction caused by the hypertrophy of the muscular walls of the systemic arterioles is the chief factor, the view always held by Dr. George Johnson.

I am in a position to state that these similar opinions were arrived at separately, but certainly Dr. Johnson has the priority.

Dr. Johnson's position is this. The muscular walls of the arterioles are excited to contract by the stimulus of the abnormal blood of advanced kidney disease. This contraction of the arterioles obstructing the blood flow leads to increased arterial tension, and this in its turn evokes hypertrophy of the left ventricle.

He has repeatedly demonstrated the existence of hypertrophy of the muscular walls of the arterioles in chronic Bright's disease, and on this anatomical fact his theory is based.

Dr. Johnson's explanation lights up distinctly the vascular changes and their indications—viz., the increased arterial tension felt by the trained finger and demonstrated by the sphygmograph, the accentuation of the aortic second sounds so commonly found in chronic Bright's disease, and forming so important a matter in erecting a diagnosis (Rosenstein, "Die Pathologie und Therapie der Nieren Krankheiten," p. 139, 2nd edition, 1870), the hypertrophy of the left ventricle, producing the usual signs, and the tendency to apoplexy from the distension (Ueberspannung) of the arteries in this condition.

I am, Sir, yours truly,

J. MILNER FOTHERGILL, M.D., M.R.C.P. Lond.

22 Lower Seymour Street, London, W.

## Medical News.

**Lady Students at University College.**—At the adjudication of prizes at University College, London, last Wednesday, the first prize in Jurisprudence was awarded to a young lady who two years ago, at the same college, achieved a like success in Political Economy. The second place in the same class was attained by another lady. Another obtained honours in Political Economy; and prizes were gained by three, and certificates by several, in the Fine Arts classes. That women should prove themselves quite equal to men in drawing and painting is, perhaps, less remarkable than their success in sterner studies; but it is noteworthy in these days when fresh consideration is being given to the question of female education. The experiment of mixed classes has as yet been only very partially tried at University College, and its extension through the whole of the Arts School would involve none of the peculiar difficulties that have been incident to the attempt to teach medicine to ladies in Edinburgh. The Senate of the University of London is soon to consider the recent vote of Convocation in favour of admitting women, on the same conditions as men, to its degree examinations. If a woman competing at college with men can take prizes in Political Economy and Jurisprudence it is hard that she should not be allowed the chance of obtaining a degree in Arts or Laws.—*Athenæum*.

**Vaccination Grant.**—The Local Government Board, on the report of the inspector of public vaccination, have awarded Dr. Waring Curran, Medical Officer of the Mansfield Union, Notts, the sum of £5 7s. 4d., for successful vaccination as performed in Dr. Curran's district.

## NOTICES TO CORRESPONDENTS.

### SPECIAL NOTICE.

THE Publisher will be glad to receive arrears of subscription for last and previous years. He regrets to state that there are still several gentlemen against whose names there are as many as four and five years' arrears standing, and who have had repeated applications for payment by letter made to them without any response. He thinks such should not be the case in an honourable profession.

Dr. W. HAYNIE, Batesville.—Subscriptions to America must be paid in advance. We can make no exception to this rule.

Dr. M., Manchester.—The gentleman named has been dead about twelve months.

Dr. S., Newington, will find the paper referred to in our number for the first of July, 1869.

Dr. ROBERTS will please receive our thanks.

COMMUNICATIONS, Enclosures, &c., have been received from Dr. Byrd, Illinois. Dr. Galvani, Bologna. Dr. Allen, Massachusetts. Dr. Milner Fothergill, London. Dr. Pavy, London. Dr. Benham, Wakefield. Dr. Albert Mooren, Berlin. Mr. Reed, London. Dr. A. D. Rockwell, New York. Dr. Sturges, New York. Mr. Collette, London. Dr. Hewett, Mr. Aston, Wadingham. Dr. Mrgan, Dublin. Dr. Brinton,

### VACANCIES.

King's College, London. The Chairs of Materia Medica and of Comparative Anatomy.

King's College Hospital. Physician, Honorary.

Owen's College, Manchester. Professorship of Anatomy. Emoluments from stipend and fees, guaranteed not to be less than £500 per annum. Full particulars on application to Dr. Greenwood.

Westminster Hospital. Resident Obstetric Assistant, without salary, but with board and lodging. Applicants must address the Secretary.

Lock Hospital (Mal.), London. House Surgeon. Salary, £50 per annum, with board and apartments.

Stockport Infirmary. House Surgeon. Salary, £60 per annum, with board and apartments. Address the Hon. Sec.

Queen's Hospital, Birmingham. House Physician. Salary, £50, with board and residence. Applications, &c., to the Secretary.

Royal Albert Edward Infirmary, Wigan. House Surgeon. Salary, £150, with apartments, but not board. Applications to the Hon. Sec.

West Norfolk and Lynn Hospital. House Surgeon and Secretary. Salary, £80 per annum, with board, lodging, and washing. Testimonials, &c., to be sent to the Weekly Board. King's Lynn.

Sussex County Hospital. Dispenser. Salary, £100 per annum, with partial board. Preliminary information of the Secretary.

### APPOINTMENTS.

Crowe, Dr. G. W., House Surgeon to the Warneford Hospital.

DENBY, T. C., M.R.C.S.E., Junior House Surgeon to the Infirmary and Dispensary, Bradford, Yorkshire.

DICKSON, H. C.M., Resident Clinical Assistant to St. Luke's Hospital, Old Street, London.

DUFF, J., L.F.P. & S. Glas., Resident Assistant Medical Officer at the Oxfordshire and Berkshire Lunatic Asylum, Littlemore.

GREENWOOD, Mr. T. P., Assistant House Surgeon to the Derbyshire General Infirmary, Derby.

HOMAN, G. W., M.R.C.S., Resident Medical Officer to the St. Pancras and Northern Dispensary, London.

LE MOTTE, G. H., M.R.C.S.E., Junior House Surgeon to the Royal Free Hospital.

M'COMBS, J., M.A., M.B., C.M., Assistant Medical Officer to the Homerton Fever Hospital.

MACNAUGHTON, J., M.B., C.M., Medical Officer for the Parish of Kilchrean and Dalavich, N.B.

MASON, W. J., L.R.C.P. Ed., M.R.C.S.E., Medical Officer to the Workhouse and Medical Officer and Public Vaccinator for No. 3 District of the Sudbury Union, Suffolk.

OGSTON, A., M.D., a Surgeon to the Royal Infirmary, Aberdeen.

PORTER, D., M.D., L.F.P. & S. Glas., Medical Officer for the Haughton-le-Skerne District of the Darlington Union.

SMITH, W. J., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer to the Rawmarsh District of the Rotherham Union.

THOMSON, Mr. J. H., House Surgeon to Gray's Hospital, Elgin.

WILL, J. C.O., M.D., C.M., a Surgeon to the Royal Infirmary, Aberdeen.

ARMY MEDICAL DEPARTMENT.—Surgeon G. C. Gribbon, M.B., to be Surgeon-Major, vice D. Wood retired on temporary half-pay. Surgeon J. J. Crean, from half-pay, to be Surgeon, vice R. Adams, M.D., deceased. Surgeon T. Wood, M.D., from half-pay, to be Surgeon, vice F. T. McCarthy, deceased.

## Marriages.

ANDREW—MACDOWEL.—On the 9th ult., at St. Stephen's, Dublin, Harry P. Andrew, late Captain 8th Hussars, to Selina Henrietta (Lina), second daughter of Professor MacDowel, M.D. T.C.D.

SMITH—JACKSON.—On the 24th ult., at Orpington, Kent, Thomas Heckstall Smith, F.R.C.S., of St. Mary Cray, to Emily, elder daughter of Addis Jackson, Esq., of Orpington.

## Deaths.

APPLIN.—On the 20th June, at Manchester, A. O. Applin, M.R.C.S.E., Staff Surgeon-Major Army.

BARRETT.—On the 16th June, at Wallingford, J. S. Barrett, M.R.C.S.E., of Kingston-Bagpuize, aged 76.

BOWKETT.—On the 16th June, Thos. Edward Bowkett, L.S.A.L., of Poplar, aged 70.

COTTERELL.—On the 19th June, Peter Ambrose Cotterell, M.D., of West Bromwich, aged 47.

HARDY.—On the 21st June, H. G. Hardy, L.R.C.P. Ed., M.R.C.S.E., of Willington, aged 48.

NISBETT.—On the 22nd June, at Lee, S.E., Sir Alexander Nisbett, M.D., B.N.

PERRY.—On the 21st June, at Helensburgh, Jane, relict of Robert Perry, M.D., aged 88.

### OSTEOID CANCER OF LEFT FEMUR.

By W. JOHNSON SMITH, F.R.C.S.,  
Surgeon to the Seamen's Hospital, Greenwich.

JOHANN ANDERSSSEN, æt. 24, admitted into the Seamen's Hospital on July 21, 1873, a tall, muscular Norwegian, slightly anæmic, his countenance indicative of constant severe pain.

Four months before admission the patient noticed a slight swelling of the left knee, which speedily became painful, and produced lameness. No history of injury or of previous disease in this part.

At the time of admission there was a regular swelling of the lower extremity of the left femur, which swelling, as it was traced upwards, could be felt gradually subsiding into the lower third of the shaft. The surface of this tumour was then quite smooth. The tumour seemed to be of firm consistence; it was tender on pressure. The circumference of the lowest portion of the thigh just above the upper margin of the patella was 16½ inches, the circumference of the right lower limb at a corresponding part being 13½ inches. There was slight fluid effusion into left knee-joint. The integument over the tumour seemed to be perfectly healthy, and could be moved freely over the hard parts below. In the left groin could be felt a round hard tumour of the size of a small apple. The patient was put on full diet, and ordered to keep to his bed.

During the month of August the tumour in the femur increased slowly in size, and became more and more painful. It remained very firm, and felt like an enchondroma. Its surface during this month became slightly lobulated. The inguinal swelling increased slowly in size, the patient rapidly lost flesh, and suffered much from pain in the thigh.

During the month of September the disease made rapid progress. The tumour in the femur increased in size, became distinctly lobulated, and became associated with

large hard irregular outgrowths (glandular), which almost completely filled up the popliteal space. The leg and foot became very dropsical, and the skin over the tumour pale, oedematous, and marked by tortuous veins. The tumour increased in length as well as in circumference, and involved almost the whole of the lower third of the femur. The patient had now become much emaciated, and had several attacks of hæmoptysis, the bleeding, however, never being very profuse.

During the months of October and November there was progressive decline, the main symptoms being emaciation, extreme debility, anæmia, occasional hæmoptysis, cough, with frothy mucous expectoration, retention of urine, necessitating frequent catheterism, acute pain in the thigh and groin, extreme distension of the skin of left leg and foot from dropsy. Large bed-sores formed over trochanter. At no period did there seem to be any tendency in the skin over the tumour to become ulcerated, or even congested.

Death on December 11th, 1873. Post-mortem examination, December 13th, 1873.

The left femur presented at its lower third a large tumour, completely encircling the bone, and extending inferiorly to the margin of the articular cartilage over the condyles, which cartilage remained quite free and healthy. This tumour was largest below, and diminished gradually in circumference as it passed upwards. The growth was of a uniform dead white colour, and firm and elastic, resembling on superficial examination a firm fibroma. The tumour was slightly lobulated in front, and posteriorly was connected with several large irregular outgrowths, the structure of which was harder than that of the main tumour (diseased popliteal glands). The tumour of the lower part of the femur measured six inches from above downwards, and the circumference of the diseased mass (including femoral tumour and associated diseased glands) was sixteen inches. Immediately above this large tumour there was on the anterior surface of the shaft of the femur a second growth of the size of a chestnut. This was very soft, and almost diffuent, and it resembled in regard to colour and consistence a small mass of soft carcinoma (medullary cancer). Along an extent of one inch above

this second and smaller growth, the shaft of the femur seemed to be quite healthy; but beyond this portion the whole of the bone, as far as the base of the trochanters, was involved in a third tumour, much lobulated both on the surface and at its margins, and having a structure similar to that of the main growth below. The surface of each growth was covered by slightly thickened periosteum, which dipped down between the lobes. The neck and head of the femur were free from morbid deposit, but the osseous tissue here was very soft. At the floor of the pelvis on the left side was a large and much lobulated mass of stony hardness. This mass, formed by a fusion of diseased glands, was of the size of a cricket-ball, and was traversed almost through its centre by the iliac vessels. The surfaces of both lungs studded with numerous flattened and disc-shaped deposits of a pale white colour and irregularly calcareous consistence. Larger and more irregularly-shaped deposits were found within the lungs in each lobe. The bronchial and tracheal glands much enlarged and hardened, forming a very hard tumour, which was traversed by the left bronchus. In front of the second and third lumbar vertebrae was an elongated and hard tumour (glandular). All other viscera healthy.

#### REPORT ON THE MORBID GROWTHS FROM THE ABOVE CASE.

By JOSEPH NEEDHAM, F.R.M.S., London Hospital.

The specimens presented for examination were—

1st. Portions of the tumour surrounding the lower third of the left femur.

2nd. Portions of diseased popliteal lymphatic glands.

3rd. Part of mass representing the lumbar lymphatic glands.

4th. Several pieces of lung tissue, in which were embedded several morbid deposits varying in size from a millet-seed to a walnut.

1st. The consistence of this mass varies considerably; the greater part immediately surrounding the bone is very hard, whilst the external portions are soft, the density increasing from without inwards. The matrix of the dense portions consists of large irregular fibres varying in size from  $\frac{1}{16}$  to  $\frac{1}{8}$  of an inch in diameter, arranged in parallel bundles, radiating from the surface of the femur to the periphery of the tumour, but also presenting in some parts a dense irregular network, due to those radiating fibres crossing each other and uniting at various angles; each of these fibres gives off at irregular intervals branches, which radiate in various directions and join other fibres and their branches. The elements of the matrix in the central portions are so closely impacted that few interspaces can be discerned; but proceeding from this position to the circumference the fibres become more and more separated, so that they form large irregular alveoli varying in size, in which the cell elements are enclosed. In the softer parts of the tumour, more especially at the periphery, the bundles of large fibres are separated by wide intervals; the large spaces thus formed are filled by masses of the softer elements. Externally the tumour is covered by a dense layer of connective tissue, from which processes representing trabeculae can be traced even into the dense central calcareous parts; but these processes are distinct from the fibres proper of the matrix, and in no place are they observed united. Tracing the fibres from without inwards their structure is seen to be—first, apparently homogeneous, then faintly fibrous, and finally, calcareous; but, although this is the predominant arrangement of their structural peculiarities, yet all the blood-vessels are surrounded by a zone of calcified fibres. No true lacunae nor canaliculi are to be seen, objectives up to  $\frac{1}{16}$  in. revealing nothing in the so-called "osseous tissues," but minute calcareous granules and a few small badly-formed cavities. The soft elements consist of spheroidal or elongated oval cells, from  $\frac{1}{16}$  to  $\frac{1}{8}$  of an inch in diameter, each containing one or two well-defined nuclei. These cells are best seen in the large

alveoli situated in the peripheral portions of the tumour; advancing to the centre, the cells become gradually smaller and more elongated, and are firmly attached to the fibres. Tracing them still further, their nuclei only are to be seen, whilst in the central calcified portions nothing approaching the character of either cell or nucleus is visible: but the cells are scattered throughout the calcareous zones surrounding the blood-vessels; closely attached to the wall, and projecting into the lumen of some of the blood-vessels, are small collections of such cells. The large peripheral spaces already described are filled with large masses of cells in different stages of disintegration; some spaces contain nothing but granular debris, in which minute oil globules occupy a prominent position, while in other spaces the cells are very granular, but little altered in shape. The tumour is not very vascular, the blood vessels being few in number and rather large in size; their walls are very thin, and are composed of fine fibrous tissue surrounded by round and fusiform cells corresponding to those found in other parts of the growth.

2nd. Not even a trace of glandular arrangement remains to indicate the original nature of the mass; it is extremely dense, much more so than the primary growth, and consists of numerous calcareous spicules radiating from the centre to the circumference, forming long, narrow meshes, wherein are to be seen, closely packed, numberless round cells, agreeing in character with—but rather larger than—those of the primary deposit. In no situation do they show signs of fatty degeneration. The glands are fused together and surrounded by a capsule composed of loose connective tissue which is firmly adherent to the mass. The blood-vessels are more numerous than in the first specimen, and their walls are calcified.

3rd. In structure these glands are identical with No. 2.

4th. The structure of these masses, small and large, corresponds to that above described. The calcareous matter is deposited principally in the fibres surrounding the vessels, which are here (as in Nos. 2 and 3) more numerous than in the growth from the femur. The stroma is more loosely arranged, and in some parts it is soft, and dimly granular, resembling the matrix of hyaline cartilage; multitudes of cells are seen filling up the alveoli of the growth and distending the adjoining air-cells of the lungs; the growth thus seen invading the pulmonary alveoli consists of round nucleated cells without stroma. All that can be discerned in these morbid masses, of the normal structure of the part, is a beautifully preserved plate of hyaline cartilage, here and there the only landmark of an obliterated bronchus. The lung tissue and the morbid deposits therein are much pigmented.

The appearance of these growths agree (with the single exception of the absence of true lacunae) with those usually described under the name of peripheral osteo-sarcoma, or osteoid cancer of Müller, and as such I should regard them.

#### REPORT ON SYPHILIS.

By C. R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.,  
Senior Physician to the Metropolitan Free Hospital.

In a previous number of the MEDICAL PRESS AND CIRCULAR I made reference to a lecture on tertiary syphilis lately delivered by Dr. Alfred Fournier, the distinguished pupil of Dr. F. Ricord, at the Lourcine, female venereal hospital of Paris.

In another lecture, reported by M. Pichard in *Le Progrès Médical*, June 6, Dr. Fournier speaks as follows of the gummy tumours of the cellular tissue:—

*Third Period—Ulcerative Stage.*—This stage is truly the most important of all those which concern gummy tumours; at any rate, it is, I think, the least well known. The tumour opens, and this swelling presented itself a little while ago in the form of a more or less extended focus, clearly fluctuating, appear as if it must at once on being opened give forth an abundant quantity of liquid, and collapse

in a proportionate manner. Now, does this take place? Not at all, as we shall see.

And, first of all, but very little liquid flows from the tumour when it is opened. Often some few drops appear, and exude, rather than flow away; sometimes a teaspoonful of liquid at most is evacuated. In the second place, does the tumour sink in like an abscess which is opened spontaneously, or by the aid of the bistoury? No again. It either collapses but little, or not at all. The tumour remains after being opened almost as it was before. And that for a good reason, for but little has come away.

What is the liquid which comes away by the perforation? Sometimes, but rather rarely, much more rarely than is generally thought, it is a viscous gelatinous liquid, of syrupy consistence, transparent or semi-transparent, of which the most specific character is to be stringy, like gum. Much more commonly it is a sero-sanguinolent liquid, yellowish, pyoid rather than purulent, containing in suspension organic detritus and particles formed by the *débris* of the cellular tissue, fatty granulations, oily or blood globules, and leucocytes. Sometimes again (but more rarely) it is a liquid, markedly purulent, greenish-yellow, or again, pus ill-conditioned and reddish.

The gummy tumour, once opened, tends to open more. The little perforation becomes larger and larger by ulceration of the skin, which is destroyed excentrically, so than in some days this little perforation in the centre transforms itself into a loss of substance circular in character, of the diameter of a lentil, or a piece of twenty centimes, of fifty centimes, or even of larger diameter.

This circular orifice occupies the most prominent and most central part, so that at this moment the tumour represents a little hill, at the summit of which a little crater has opened. Now, if at this time we examine the interior of the crater, we see at its orifice a sort of parenchyma, solid, whitish, of variable whiteness (greyish or yellowish white), fleshy, and whose aspect may be compared with the flesh of the cod-fish. If we examine this parenchyma carefully, we notice that it presents the appearance of dead tissue; it is insensible, and disunited; it falls into fibrous pieces, as in this specimen, where you see some fibrillæ, of the size of a thread of vermicelli, separated spontaneously from the total mass. This parenchyma is the tissue of the tumour itself; but it is degenerated tissue mortified, passed or passing into the condition of a slough. The greater part of the tumour is made up of this solid mass. It is for this reason that it has given forth so little liquid when it opened, and has little diminished in bulk. Thus, this tissue holds with regard to the living tissues the part of a slough; it is a dead tissue which nature must get rid of. And such is indeed the final cause of all the phenomena which ensue.

Now, gentlemen, how goes on the progressive work of elimination of this gummy slough? Very simply. From day to day larger or smaller flakes are detached from the total mass, and become dissociated, broken up, and dissolved by ulceration. We find them in the pus when we examine it with care, or on the dressings; so that the total mass diminishes day by day, the tumour falls away, and at a certain epoch the fleshy mass will be completely evacuated.

When the slough comes away what remains of the tumour? Nothing but a loss of substance dug out of the healthy tissues. Now, this loss of substance, more or less profound, circumscribed by the prominent edges which surround the circumference of the tumour, constitutes a true cavity hollowed out in the healthy tissues, and has received the name of *gummy cavity*. This cavity, by the progressive ulceration of its edges, is not long in converting itself into an ulceration open to the air.

After this the gummy tumour is brought to the condition of an ulcer of dimensions varying according to the initial volume of the tumour.

What are the characters of this ulcer? It is an ulcer excavated, very hollow, even sometimes with edges sharply cut, as with a die, sometimes prominent, and raised above the surface, because still infiltrated with gummy products.

This ulcer is surrounded by an areola of a dull red hue. It furnishes a rather abundant suppuration, which is often sanious, or sero-sanguinolent, and full of organic detritus.

Up to this time nothing special in this collection of characters, nothing more than what is seen in a number of ulcers, and notably in tertiary syphilitic ulcers. But let us examine the base of the wound. The base alone of the ulcer, without presenting anything pathognomonic, nevertheless has certain characters specific enough to be easily recognised. It is above all the base of an ulcer of bad aspect and suspicious countenance. On the one hand it is irregular, areolar, and anfractuous, presenting here and there depressions. On the other hand, this ulcerated base is covered with adherent detritus, with fleshy shreds which are dead and putrilaginous; one would think it was a wound which is in gangrene here and there. This aspect is due (you have already understood) to shreds of the gummy tissue not yet detached.

By reason of these different characters, and especially on account of this evil aspect, the gummy ulcer has sometimes been able to be taken, at any rate, at first sight, for a cancerous ulcer. Several observations show that the error has been committed. This appearance, however, remains but a very short time. However little art assist, the gummy ulcer is soon cleansed and enters into the stage of reparation.

*Fourth Period—Reparation.*—Some words will suffice to characterise this ultimate stage. When the last gummy *débris* are eliminated the ulcer becomes clean and has a better look; its edges sink; the red areola diminishes; the base rises and becomes covered with fleshy granulations; the pus becomes better, greener, and like that of simple wounds. Then a work of cicatrisation ensues, identical with that which takes place in any wound, and in a variable time the definitive cicatrisation takes place. The scar which results is first of all red; it next becomes paler, and white. It is always depressed by reason of the loss of substance of an irreparable character which the integuments have undergone.

Such is the evolution of the syphilitic gummy tumour in the simplest cases, such the evolution we may call normal.

This evolution we may sum up in a few words, to retrace the whole of the different phases of which we have been speaking.

*First Period.*—The gummy tumour is seen in the form of a tumour, solid, hard, cold, indolent, and not inflamed.

*Second Period.*—This tumour softens, and becomes fluctuating. Then a sub-inflammatory process takes possession of it; the tumour becomes reddish, and simulates in some of its shades a phlegmonous abscess ready to open.

*Third Period.*—The tumour opens, ulcerates, eliminates its slough, then, by the destruction of its cutaneous covering, converts itself into an open ulcer, of bad aspect, still covered with shreds of gummy material.

*Fourth Period.*—This ulcer cleanses itself, is converted into a wound of better appearance, then is repaired and cicatrises. In this is resumed all the pathological history of the gummy tumour.

And in how long time are there produced these successive phases of the gummy tumours. What in a word is the duration of the gummy tumour?

1. On the one hand this duration is always long; it never is less than some months, three to four months at least—six to eight months on the average—sometimes longer.

2. On the other hand, this duration is very variable. The varieties above all are in the two first periods, and especially in the first, for the two last (at least in general and making reserve for certain cases to be spoken of soon) evolve themselves in a pretty regular way, pretty equally and relatively rapidly.

The first period, or period of formation, is above all unequal with regard to its duration—sometimes rather short, at others slow, extremely slow. There are cases where the gummy tumour, when formed, remains stationary

for a very long time, without apparent modifications—and similarly for the second. There are some gummy tumours which quickly soften; hardly are they formed before they fluctuate. There are some which soften very slowly and partially, this taking place in various isolated parts of the tumour.

On the other hand, once the peripheric inflammation has declared itself, things go on pretty quickly and pretty equally in different patients. A few weeks suffice to empty the gummy tumour and to bring it into the state of an ulcer. In the ulcerated condition, it may remain a shorter or longer time, but however little a treatment merely topical be employed, the cleansing and reparation of the ulcer is produced pretty promptly.

*Varieties.*—What I have until now described is the gummy tumour in its simplest form and its most elementary type, without any accident or complication. Now, to be faithful to what we see at the bed-side, we must add that the gummy tumour does not always present itself in this typical form. It is subject, on the contrary, to certain varieties of symptoms and of evolution which I ought to point out. I will only indicate to you in this chapter of varieties what is the most essential, certain that your medical education will fill up the unavoidable omissions in this short *résumé*.

Among the variety of symptoms, two points alone are worthy of arresting our attention—

1. I have represented to you the gummy tumour as a tumour essentially indolent, not causing of itself any pain, and insensible to pressure. This is the case, in fact, in the majority of such tumours, at least in 95 in 100 of them. But you ought to know also that in certain cases this tumour, far from being indolent, determines on the contrary rather severe pain, even violent and acute pain.

And when does this take place? In a solitary instance: when the tumour is in relation with a trunk of a nerve or a nervous filament which it compresses or surrounds. You will find numerous instances of this in science. Thus, M. Ricord had a case where a gummy tumour in the groin exerted severe pain of crural neuralgia, and irradiated all over the thigh from the groin to the knee; whilst in another case, seen by the same author, two gummy tumours seated in the course of the ulnar nerve provoked severe pains radiating over the forearm and the two little fingers, thus following clearly the distribution of the nerve. In a case of Nélaton's, a gummy tumour in the axilla caused rebellious neuralgic pains of all the limb in the shoulder. In another case, well studied by Zambaco, a tumour seated on the forearm, in the region where the pulse is felt, caused pain of the anterior aspect of the three first fingers and pains radiating upwards to the shoulder.

2. I have told you that in the majority of cases the gummy tumour did not of itself cause any functional annoyance. This is the case in all instances where this tumour is neither injurious by its size nor its situation.

But it is quite different in opposite conditions. It is useless to say, for instance, that a large tumour becomes by its volume alone the origin of functional disturbances, or again, that a tumour seated on a movable part, such as the jaw or the hand, may prevent motion. A voluminous tumour seated in the submaxillary region prevented the patient from eating, and even impeded respiration and deglutition from the compression which it exercised on the pharynx.

*A fortiori*, when a tumour is in the vicinity of a nerve, it may cause, besides neuralgic pains, functional disturbances of more or less important character? In Zambaco's case the patient, who was employed in ironing, experienced, from the gummy tumour seated in the region of the pulse, congestion of the hand, and such a diminution of muscular power that she could no longer hold her iron. In Nélaton's case the gummy tumour in the axilla caused very severe pain, a swelling of the whole limb, fornication, and a notable diminution of muscular power.

But all of these have but a secondary interest; all

these varieties of symptoms might have been foreseen. On the contrary, the following is of more importance to be known:—

*Variety in Number.*—In the most frequent cases we observe either a single gummy tumour, or again, two, three, or four such at most on the same patient. It is far rarer to see a greater number of these tumours.

But in certain cases, and notably in patients rudely assailed by malignant syphilis, we meet with multiple gummy tumours, and when these tumours commence to multiply they multiply with strange facility. This is a true gummy diathesis. We then see eight, ten, twelve, or fifteen at the maximum, of unequal volume, disseminated, and of different degrees of development, or reunited in groups. One of our patients had a group of six tumours on the back. As another example of these tumours, remember the case of that patient I showed you in our first meeting: she had four tumours on the head, three on the legs, two on the forearm, and one on the spine of the scapula.

This is not all; but from this moment we leave usual cases, and enter the field of exceptions. In some patients, even more numerous gummy tumours have been seen—twenty, thirty, thirty-five, fifty. M. Cazenave has mentioned a patient whose arms and shoulders were covered with gummy tumours: "There were certainly more than fifty." The two arms presented the strangest appearance; they were quite knotty, and presented a coppery colour, very marked; some of these tumours were hollowed out by characteristic ulcers.

M. Corvisart has mentioned a patient who presented with several other lesions incontestably syphilitic more than 100 tumours on the breast, belly, and arms. Indeed, there is more yet, and here we enter quite into the extraordinary:—

You will find in the *Bulletin de Thérapeutique* of 1845 a case related by Lisfranc, in which a patient had on the arm, forearm, and thighs, 160 gummy tumours, and these tumours were large, would you believe it? The smallest were the size of a little hazel-nut, and the largest that of a small pear. Iodide of potassium was given. In eight months of treatment there remained only forty tumours; the 120 had been cured by resolution. If we suppose this case to be authentic (I mean not amenable to objections with regard to the nature of the tumours) we must none the less take it for a fact completely exceptional, a true pathological curiosity.

But much otherwise important are the varieties of volume about which it remains for me to speak.

*Varieties in Volume.*—I have brought before you the gummy tumour as usually being of small volume, about a walnut in size; I have also added that the volume may be considerable (that of a hen's egg or turkey's egg). Now, in some rare cases, this volume may be surpassed, and greatly. To cite only two extreme cases, I have observed a gummy tumour of the thigh measuring eight to ten centimetres in diameter horizontally, and fourteen vertically, with a thickness varying from two to six centimetres, i.e., a tumour as large as the half of a fetal head. Dr. Mendeville has seen at the Val-de-Grâce a gummy tumour still larger; this was on the head. It descended from the orbit to the neck, which was attacked for a length of five to six centimetres; setting out from the nose it went as far as the occiput, that is, the lower half of the face, a great part of the neck, and all the lower part of the cranium were converted into an enormous gummy tumour.

Facts like this, though rare, are of importance to be known; and I point them out more willingly since they are but little known in general, and have not as yet, as we may say, right of sojourn in science, if we may judge at least by the silence of our classic writers on the subject. As to the interest they excite, you will understand it without my pointing it out. On account of their rarity and their excessive volume these tumours are apt to be taken for tumours of another nature—for malignant tumours, and especially cancers, and hence they are apt to be subjected to grave surgical treatment. The proof is, that in the two

cases I have just cited, the diagnosis of cancer had been at first made by different practitioners; in the one an operation had been proposed; in the other, very fortunately for the patient, this supposed cancer had been declared not to be fit for operation. It got well under iodide of potassium.

(To be continued.)

## MEDICAL PROBLEMS OF THE DAY. (a)

BY NATHAN ALLEN, M.D.

(Continued from page 3.)

**Physical Development.**—A gradual change is taking place in the organisation of our New England people, with which the members of the medical profession cannot but be conversant. This is very manifest from the change in the type and character of disease. Formerly there was relatively more acute disease and less chronic—more violence in the attacks, with a higher grade of inflammation. It required in its treatment frequent venesection and more powerful medicine. At the present day we have a larger class of diseases arising from general debility, from indigestion, anæmia, scrofula, neuralgia, &c. This change indicates the existence of less muscle—more nerve—less physical vitality—more nervous energy—less power of endurance, but more mental activity. The same change is also indicated in the anatomy and physiology of the person. The framework of the body generally is not so large—is not so compact, nor so well proportioned; the countenance is paler, the features are more pointed and not so expressive of health, though more so of intelligence. The texture or quality of organisation is more delicate and refined; the brain is becoming developed more and more relatively, and too frequently at the expense of the body; or, in other words, the nervous temperament, with all its advantages and disadvantages, is becoming too predominant for other parts of the body. As one of the consequences we have more diseases of the brain and nervous system, more sudden deaths from apoplexy, paralysis, and also from diseases of the heart. The average duration of life may as a whole be longer, but this arises from less exposure, better care, and improved medical treatment.

This change in organisation has occurred principally within the last two or three generations. Some of its causes are very obvious, while others are more obscure and complicated. Among the principal causes may be mentioned less exercise of the muscles out-doors, on the farm and in mechanical pursuits, but more exercise of the brain in the school-room, in the shop, in the store, in the factory. The change in the construction and manner of heating our dwelling-houses, causing a much higher temperature—the increasing strife and competition in business, the general style of living and modes of dress, &c., have also had much to do in producing this change. These and other causes have exerted a pernicious influence upon the female constitution, and so upon the laws of inheritance. It is through this medium or channel especially, and by means of these laws, that, in the course of two or three generations, great physical changes are effected. The laws of heredity constitute the most important agency whereby the vital forces, the vigour and soundness of the physical system are changed for better or worse. Thus in the course of time is determined the peculiar type and character of a people.

There is nothing of such transcendent importance to a race or nation as *physical stamina*—strong, vigorous, healthy constitutions. How did the Germans, in the late war, gain such signal victories over the French? Why does that people now stand at the head of all the European nations in power and statesmanship? Why do the Germans

take the lead at the present time in the cultivation of the sciences, and in almost every department of literature? Is it not owing to their grand *physique* more than to any thing else?

**Mental Culture.**—In the advancing knowledge of physiology it has been discovered that all mental culture should be based upon the brain—that education should be pursued in harmony with the laws of life and health, and that where these are violated, the advantages of the former afford poor compensation. Formerly no school boards and teachers, in the matter of education, gave much attention to the condition of the body or the development of the brain; and even at the present day very little is paid them, compared with what should be given to those great physical laws which underlie all mental culture. The lives of a multitude of children and youth are sacrificed every year in this Commonwealth by violating the laws of physiology and hygiene, through mistaken or wrong methods of mental training; besides, the constitution and health of a multitude of others are thus impaired or broken down for life. Nowhere else in society is a radical reform needed more than in our educational systems. Inasmuch as the laws of the body lie at the foundation of all proper culture, they should receive the first consideration. But in educating the boy or girl, from the age of five to fifteen, how little attention is given to the growth and physical changes which necessarily occur at this most important period of life! The age of the child should be considered, the place of schooling, the hours of confinement and recreation, the number and kinds of studies, together with the modes of teaching, should all harmonise with physical laws—especially those of the brain.

The system or mode of treating, in education, all children as though their organisation were precisely alike, is based upon a false and unnatural theory. Great injury, in a variety of ways, results from this wrong treatment; in fact, injuries are thus inflicted upon the sensitive organisations and susceptible minds of young children from which they never recover. That many of our most independent and clear-headed educators themselves express so much dissatisfaction with the working and results of our schools, affords evidence that something is wrong in the present system. As we contemplate the great improvements made in education for the last thirty or forty years, and are surprised that educators were content to tolerate the state of things then existing, so will the next generation, when still greater and more radical changes shall have been introduced, look back with astonishment at this generation, and wonder that it was so well satisfied with its own methods. When our educators become thoroughly convinced that physical development as part of education is an absolute necessity—that a strict observance of the laws of physiology and hygiene is indispensable to the highest mental culture, then we shall have vital and radical changes in our educational system; then the brain will not be cultivated so much at the expense of the human body, neither will the nervous temperament be so unduly developed in proportion to other parts of the system, now so often bringing on a train of neuralgic diseases which cannot be easily cured, and exposing the individual to the keenest and most intense suffering which all the advantages of mental culture fail, not unfrequently, to compensate.

The more this whole subject is investigated, the more reason we shall find for making allowances or some distinction in scholastic discipline with reference to the differences in organisation of children, and for adapting the hours of confinement and recreation, the ventilation and temperature of schoolrooms, the number and kinds of studies, the modes of teaching, &c., to the laws of the physical system. But another and still more important change must take place. Some time—may that time be not far distant!—there will be a correct and established system of *mental science*, based upon physiological laws; and until this era arrives, the modes and methods of education must remain incomplete and unsatisfactory. The principles of this science, in the very nature of things, must rest upon a correct knowledge of the laws and func-

(a) Part of the annual address before the Massachusetts Medical Society, assembled in Boston June 5rd.

tions of the brain ; and until these are correctly understood and reduced to a general system, all education must be more or less *partial, imperfect, and empirical*. While the old theories of metaphysicians are very generally discarded, they still have practically a powerful influence in directing and shaping our educational systems and institutions. In the selection and arrangement of studies very little attention is paid to the peculiar nature or operations of the various faculties of the mind, or the distinct laws that govern their development and uses. For illustration—instead of educating, drawing out, and training, all the mental faculties in their natural order and in harmony, each in proportion to its nature or importance, the memory is almost the only faculty appealed to in every stage of education ; and this is so crammed and so stuffed that frequently but little of the knowledge obtained can be used advantageously. Instead of developing the observing faculties by “object teaching,” appealing to the senses of sight and hearing, those two great avenues of knowledge, or giving much instruction *orally*, we require the scholar to spend most of his time in studying and poring over books, mere books. The mind is treated as a kind of general receptacle into which knowledge almost indiscriminately must be poured, yes, forced, without making that knowledge one's own, or creating that self-reliance which is indispensable to its proper use. In this way the brain does not work so naturally or healthily as it ought, and a vast amount of time, labour, and strength is wasted—nay, worse than wasted. From this forced and unnatural process there often results not only a want of harmony and complete development of all parts of the brain, but an excessive development of the nervous temperament, and not unfrequently an irritability and morbidness which are hard to bear and difficult to overcome ; and not unfrequently it ends in a permanent disease of the brain, or confinement in a lunatic asylum.

When we take a careful survey of the various discussions and diverse theories on this subject, considered metaphysically, and then compare them with the great improvements and discoveries in the physical sciences for the last fifty years bearing upon the same subject, the change or progress looks mainly in one direction—viz., that all true mental science must ultimately be based upon physiology. Here is a great work to be performed, and when accomplished it will constitute one of the greatest, most valuable, and most important achievements that was ever wrought in the history of science. A vast amount of positive knowledge has already been accumulated on this subject by various writers, but a great work, by way of analysis, observation and induction, and of further discoveries as to the functions of the brain, remains to be completed. The work must be performed in a great measure by persons profoundly versed in the physical sciences ; and no small proportion of it must come from the observations, labours, and contributions of medical men.

*The Temperance Question.*—Probably there is no one subject agitating the public mind at the present day so important as that of temperance. Aside from its economical, political, and moral bearings, it sustains a most vital relation to medicine. In some respects it is really a physiological question, the solution of which belongs to the experts in this science ; but unfortunately there is not here a general agreement of opinion. Before this reform can be carried on very successfully, the exact relations of alcohol to health and disease must be better understood and positively settled. What is the physiological action of alcohol on the human system in health and disease ? Does it increase or impart force in the process of digestion ? Is alcohol in any of its forms absolutely necessary as a therapeutical agent ? Is there such a love of stimulants implanted by Nature among our instincts, that man cannot well resist temptation ? Does health require as a common beverage, at meals, or other times, the use of a mild stimulant ? These and kindred questions must be settled, not by mere authority, nor by individual opinions, but by such an accumulated amount of evidence derived from the study of physiology and pathology, that it cannot

be disputed or resisted. How important that the members of the profession, who are the proper expounders of these sciences, should become safe teachers and guides in settling these grave questions ! But whatever differences of opinion may here exist, there are points of view in regard to this reform upon which there should and must be entire agreement—viz., its sanitary aspects. That intemperance is productive of a vast amount of disease, all will admit ; that it is one of the most powerful causes of physical degeneracy now in operation, no one will probably question. If to alcohol we add tobacco, opium, and other stimulants and narcotics, no pen can describe the terrible injuries which they inflict upon the human race.

From a hygienic point of view, of what avail are the benefits of good air, pure water, wholesome food, healthy occupations and dwellings, when the laws of the physical system are being constantly violated by the poison of alcohol and tobacco ? It is not alone the present or temporary effects of these agents, but the *permanent*, such as are incorporated into the organisation itself and become a part and parcel of it—these are the seeds of evil tendencies and diseases, which are transmitted to successive generations. It is only when we take into account the power and extent of hereditary influences that we can fully appreciate the importance, the magnitude, and the grandeur of the temperance reform.

*Position of Woman.*—That the marriage and parental relations constitute the groundwork, the main pillars of human society, requires here no argument to prove. The physiological law of *sex* is the corner stone of these relations, and has, we believe, a far more direct and powerful influence upon organisation and character than is generally considered. Inasmuch as woman is so created that her own health is very much affected by this feature in her organisation—inasmuch as the physical development of offspring is also very much dependent upon her constitution, these two considerations have an important bearing upon her education, employment, and relations to the public. There is a normal and healthy standard for every organ in the human body ; and whatever influences tend to change or violate the laws that govern any one of these should be carefully guarded against. Thus, in the matter of education it has been very clearly demonstrated by a distinguished member of our profession, that the boy and girl cannot be educated alike. No one but an experienced physician can realise or describe fully the powerful influences which the function of menstruation has upon the health of women ; but this effect, in extent and character, depends much upon the early stages of its development. For the period of some thirty years there is certainly a marked difference in the sexes, which must materially interfere with employments and public duties. Such is the relation, too, of this function to the nervous system, that any derangement or morbidness of action here may affect the disposition and character of the individual.

All writers on physiology agree that too much importance can scarcely be attached to the healthy action of the uterine functions ; and when we present the testimony of one writer, it expresses, we believe, the opinion of all. Says Colombat : “The extreme sensibility of the uterus, its physiological importance, its peculiar irritability, and especially its more or less sympathetic connection with other parts of the body, render it a centre of action which in the sex seems in a measure to *domineer over the whole economy*, and form the *principal basis upon which the edifice of the whole organisation rests*.”

In settling, then, the points involved in the questions of “Women's Rights,” so called, the physiological bearings and tendencies should receive primary consideration. The immediate change produced, however, may not be so noticeable, but in the course of two or three generations its effects become very striking and powerful.

That in the present state of society there is need of some changes or reform looking to improvement in the health of woman, is evident. The very general ill-health of American women is often asserted. There should certainly be a re-

form in the fashion or style of dress ; it should harmonise with the laws of the physical system. In the early training of girls the greatest care should be taken to secure the best possible development of the body ; and in the whole course of their education, whatever interferes with healthy action or violates physiological laws, should be scrupulously avoided. As to the higher departments of education and a more extended range of employments, there are substantial reasons and arguments deduced from physiology itself why woman should have these advantages. Let her have the highest culture—physical and mental—consistent with her whole nature. But then, that she should share equally with man in all the strife and competition of business, in the excitement and rivalry connected with political and public life, including suffrage, is physiologically unnatural, abnormal, a violation of the laws of her physical system. In the language of the most distinguished writer on psychology in Great Britain, “she will then have lost her feminine attractions, and probably also her chief feminine functions.” One of the cardinal points in attachment between the sexes is, that certain opposite qualities or traits of character attract each other and form the most happy unions. Now, if the qualities and traits of character in woman are to be assimilated to those of man, what will be its effect upon matrimony and harmony in married life ?

In all the situations and pursuits of life the Almighty has established bounds or limitations beyond which woman cannot go without defeating the primary objects of her creation. The reasons are obvious. It gradually changes her organisation. By a physiological law of supply and demand, Nature, in the case of woman, makes certain drafts monthly upon her constitution. That this law of periodicity be properly observed is indispensable for good health and the highest development both of body and mind. Again, if the brain is relatively exercised too much, the body suffers ; so of the brain alone, there cannot be a steady strain upon certain portions of it without impairing the functions of other parts. Maternity is a primary law in her creation. Physiology, pathology, records of health, disease and mortality establish the fact that this is her *normal* state. In the observance of this law, certain physical conditions are indispensable ; there must be a proper development of those portions of the body concerned in this function ; neither can they answer the demands nature makes, if kept constantly impoverished.

(To be continued.)

## INDIAN MEDICAL NOTES.—No. XX.

(FROM OUR SPECIAL CORRESPONDENT.)

MEERUT, UPPER INDIA,  
May, 1874.

### “SOCIAL.”

UNFORTUNATELY, there's not a copy of Murchison in the station to find out what the connection is between rheumatic and enteric fever—so often forced on attention. Do persons catch enteric a second time ? What are the distinctive differences between it and remittent fever ? Thanks to leeches, mercurial inunction, shaving the head, to which ice for ten days and nights has been kept applied, wet sheet, inunction of the bowels, seidlitz powders, castor-oil enemata, the long tube to relieve meteorism, acetate of lead and morphia to control diarrhoea, at one time strychnine and galvanism to counteract constipation, at another, Peruvian balsam for the bed-sores, and the diet iced milk and madeira, four visits a day through the blinding, blazing sun—the case is now in hand, and as the flirt soon tires of one love, the interest now inclines to another enterical flame just encountered. Then, again, why do pulses go down to 40, and lower, or intermit during convalescence. To-day tried a tent for the sick ;

it was too hot, 106° at 4 p.m. Although a certain medical epicure has not the work required, he sends an interesting book with a very affecting passage interlined, which brings back memories of the Trafalgar, at Greenwich, in days of yore. “The dinner is to consist of turtle, followed by no other fish but whitebait, which is to be followed by no other meat but grouse, which are to be succeeded by apple fritters and jelly, pastry on such occasion being out of place. With the turtle, of course, there will be punch ; with the whitebait champagne ; with the grouse claret ; the two former particularly well iced. No other wines, unless a chance bottle or two of port, if particularly wanted. Take care there is cayenne, with lemons cut in halves, not in quarters, within reach of every one, for the turtle ; also brown bread in abundance for the whitebait. The dinner to be followed by ices and a good dessert ; after which coffee, and one glass of liquor each, and no more, so that the present may be enjoyed rationally without inducing retrospective regret.”

This passage is not inserted for padding ; there are materials more than enough in daily occupation and experience. India is a grand country for the doctor who cures his patients besides keeping his own health. This is the merry month of May, which might all be spent at Simla if the mornings at Meerut were not so delicious, the hospital work so interesting, the resources so numerous that a teetotaler and almost a vegetarian really prefers to stop here. Writing these “Notes,” however, is such a constant and interesting stimulus to middle-aged faculties of observation and reflection, that leave will be asked for shortly to prow about the country somewhere or other, and then to live the holiday over again on paper. Mess-living, including an occasional guest, and doing the thing comfortably, costs about £14, servants about £5, house-rent and expenses, say £5 ; horses, sundries, about £10 more—total, £34 a month ; or, not to put too fine a point on it, £40 will see a bachelor fairly through. Some live on a good deal less ; some spend much more, with nothing to show but dyspeptic faces. Every bachelor has his own secrets, which may prevent saving. Some, however, send so much a month to various investments in the country bringing in 5 per cent. Sir Astley Cooper said his life was a very pleasant one, to chat with a number of well-bred people every morning and send up to the banker a round sum periodically. In India, when patients do not die, the doctor's life is also very enjoyable. The pay of a surgeon ranges from 317 to 451 rupees ; of surgeon-major from 789 to 1,093 rupees ; whilst a deputy-surgeon general receives 1,800—that is, £180 a month. The married man's wife may be in the Hills, his children at school in England, whilst he lives alone *en garçon*, three establishments to pay. Take things all round, the married men, although frightful grumblers, have the best of it if they have married the right sort and both are blessed with health. The married doctor meets also with great consideration. It may not be out of the way to describe a day here—for instance, yesterday : Up at 5, ride to barracks, look in at the latrines, cook-houses, and married quarters ; inspect the men very critically, finding fault if the lavatories are not used, and admitting into hospital any man who looks ill. May and June are the months for heat-apoplexy, especially on pay-nights, therefore always be prepared, for delay means death, or paralysis. At the hospital, every man reporting sick should have his temperature taken. A soldier will come up for a dose of medicine feeling stupid, has a touch of the diarrhoea, dirty tongue, offensive breath, inability to sleep, pain in the back, wind in the stomach. The thermometer to be used at once for diagnosis ; also find out the patient's history, and if you hear of cerebral affections, convulsion, scarlet fever, or any renal mischief, no matter how long ago, shave his head at once, and clap on ice immediately. After visiting the men in their wards, the women and children in an adjoining building, arranging books, documents, &c., see that the punkahs are properly pulled, the tatties watered. It may so happen that the natives

are not all there, or a father will send a young child to do a man's work. Close doors from 8 to 5, and make a disturbance if the thermometer runs above 86°. Then ride to your house, a mile distant, shaded by an umbrella. The mail is in—letters, bills, medical papers—reading this, and after that, to breakfast with what appetite you may muster to attack the delicious water-melons, strawberries, or any other light food, followed by a sleep and another visit to the hospital, to see if all directions are being carried out. Next, as it so happened, there was a lunch to ladies at the mess, succeeded by badminton indoors in the palatial halls of a medical colleague—a festive soul who, like many others, keeps young by having pleasant people and pretty faces ever about him. The second tub was succeeded by the evening visit to hospital, where a case of uterine hæmorrhage, in addition to others, required attention. Afterwards a married officer gave a very pleasant dinner party, and though music is rarely heard—for pianos as well as voices feel the climate—one lady sang with great taste and pathos, and one worthy clergyman tootled on the flute whilst old officers talked of John Company—bonuses and off- reckonings. As the dog-cart was at the door it was no trouble again to visit a certain patient whose condition was critical. You cannot visit the hospital too often in India to ensure that when you turn your back others do not follow suit. Then, the day concluded, "tired Nature's sweet restorer, balmy sleep," was sought on the couch in the garden. Some roost on the roof, a dangerous experiment for the weighty and the corpulent, who might tumble through, as on treacherous ice.

## Transactions of Societies.

### DUBLIN MEDICAL SOCIETY.

! DR. GORDON presided at the meeting on May 13th, 1874.

DR. C. E. FITZGERALD read a paper, by permission of the Council, in the course of which he described the ophthalmoscopic appearances of the optic nerve in cases of cerebral tumour, and related an interesting case which he believed to be one of cerebral tumour.

DR. HENRY KENNEDY then communicated a paper on  
**INTESTINAL HÆMORRHAGE IN FEVERS.**

He began by quoting Dr. Stokes's remark of recognising the importance of bringing together the several symptoms in which the types of fever agreed with each other. With other authors it was the differences which prevailed that were insisted on; but Dr. Stokes thought the points on which they agreed were of more consequence to be known, and the author, following out this idea, asked the attention of the meeting to the subject of hæmorrhage, which he hoped to prove was not confined to any special type of fever. For the purpose of description he would divide these hæmorrhages into three classes—first, those met in childhood or youth; secondly, those occurring in typhus fever; and lastly, those complicating enteric fever. As examples of the two first, the author detailed some cases where, though a fatal result occurred after there had been hæmorrhage from the bowels, still, on post-mortem examination no ulceration whatever was found; and in one very remarkable instance a large quantity of semi-coagulated blood was found lying in the upper part of the ilium. None had passed outwardly, nor could the closest examination detect any ulceration whatever, or any affection of the glands of Peyer. The author considered the occurrence of hæmorrhage of this kind, without any absolute lesion, as a point worthy of more attention than it seems to have received, and he had little doubt that a something similar occurred also in enteric fever, though it was not to be questioned that the source of the bleeding sometimes was from the opening of a vessel in an ulcer. The question of the actual source of the bleeding the author thought was one of practical importance, for, according as it was looked upon as an exudation or from a vessel the remedies used would have to be altered, and so a medicine

such as turpentine might prove very useful in the one case and very injurious in the other. In the course of his remarks the author drew attention to the fact that the hæmorrhages of which he had spoken were much more common at some periods than others; thus, during the past winter and spring, the number of hæmorrhagic cases in Dublin was very great, as all knew who attended the meetings of the Pathological Society. Drs. Stokes, Hayden, Foot, Moore, Nixon, and others, had all exhibited specimens, and some of these gentlemen more than one. The localities, too, in which this class of cases occurred varied much; thus, in London they seemed to be very much more common than elsewhere—it had been stated as high as one in three. Possibly, however, this was an exceptional case. The author further stated that his experience of the results of these hæmorrhagic cases entirely agreed with what had been noticed long since by Graves, and concurred in by Trousseau—viz., that they were not at all so fatal as might at first be supposed. In his own experience the author had tabulated very nearly fifty cases, and amongst these the deaths were as near as might be one in four, which, considering the very serious character of all such cases, must be considered very favourable. The author regretted that the cases he had seen had not been as accurately distinguished from each other as was to be desired—that is, as to the type of fever. He wished also to state his conviction that cases of typhoid fever in private were more fatal than those seen in an hospital, just as was known to be a fact as regards typhus fever amongst the poorer and the middle or upper classes. On this point he wished to speak with some reserve, but such was his impression. In concluding, the author gave a *résumé* of the different questions noticed in the paper, and drew attention particularly to the special source of the bleeding in the cases brought under notice, on which he said he would be very glad to hear the opinions of the gentlemen present.

DR. DARBY said he had a number of cases in 1848, and then he saw for the first time bleeding in connection with typhus fever. The cases he had were, strange to say, different from the fever which he saw in the Dublin hospitals at that time; but he had some genuine cases of maculated typhus, and also some cases of jaundice. He would not call it yellow fever—for nothing could be more yellow than the skin—but there was no black vomit. One of these cases was that of a stout man who was admitted with maculated typhus fever, and on the 13th or 14th day he had a quantity of hæmorrhage, some of it in clots. He made a good recovery. He (Dr. Darby) had about eight cases of that kind within a period of six weeks or two months, and all of them terminated in the same way, with what he believed to be a critical hæmorrhage. He never saw a case in which there was hæmorrhage in the latter stage of fever result in death. He had not known of a case in typhus fever where there was hæmorrhage in which the patient died. He had seen one case, and only one that he could recollect, of hæmorrhage which he believed to be due to ulceration in typhoid or enteric ever that resulted fatally. It was that of a child 9 or 10 years of age, and he attributed death to the bleeding from the ulcers in the bowels. At the post-mortem examination he came to the conclusion that the child died from exhaustion occurring from the simple hæmorrhages. As far as his experience went, he thought that hæmorrhage was rare. He had seen bleeding of the nose occasionally, but never as a critical evacuation. The cases of genuine typhus fever that he had in 1848 and 1849 lasted three or four months, and he had not seen cases since.

DR. HAYDEN said it seemed to him that they should be a little cautious in accepting Dr. Henry Kennedy's conclusions as to the symptoms of hæmorrhage in fevers. No doubt many examples might be quoted. Dr. Kennedy had enumerated a few in which a fatal issue had not followed the occurrence of hæmorrhage in fevers. It was notably the case in typhus, and occasionally occurred also in typhoid. Dr. Hayden thought, however, that such cases constituted by far the smaller number, and notwithstanding Dr. Kennedy's conclusions, and his high authority on the subject, he (Dr. Hayden) confessed he regarded the occurrence of hæmorrhage in fever, especially typhoid, as a very unfavourable omen. He had seen cases of hæmorrhage in typhoid fever in which no ulceration occurred. One of these cases Dr. Kennedy had alluded to, where death followed a rapid flux from the large intestine. There it would have been very desirable to have diagnosed the absence of ulceration and the source of the hæmorrhage, and that would have been a case undoubtedly

where turpentine might have been used with good effect. In many cases where evidence of existing ulceration had been in the highest degree inconclusive, the post-mortem evidence had been satisfactory in proving its presence in an extreme degree, so that the absence of symptoms which might lead one to the conclusion that ulceration did exist would not warrant one in concluding that there was no ulceration. He thought from what he had seen of those cases he should rely more upon the range of temperature and rate of pulse as evidence or to the contrary of ulceration than upon any other evidence whatever. In a case that he had himself witnessed in the course of the last session, the range of temperature was never above 103°, and the pulse was never remarkably irregular. In that case the hæmorrhage was so copious that it saturated the bed, and flowed over the floor of the ward in which the patient was lying. The man sank rapidly and died. He should fear to encourage the impression, to form which Dr. Kennedy's paper would lead any medical man, that hæmorrhage should not be regarded as a formidable symptom in fever. He (Dr. Hayden) thought it was a formidable symptom, and the cases in which it had been found not to be a fatal indication were small in number. He knew of two cases that had occurred in females under twenty years of age in which the hæmorrhage was very copious.

Dr. GORDON (the chairman) quite agreed with Dr. Hayden in thinking that hæmorrhage was a most formidable symptom, and with regard to those cases that he could recall to his mind as having recovered, their restoration to health was almost marvellous. Their recovery took place when all prospect of recovery was against them. He quite agreed with Dr. Kennedy as to the mixed character of the cases in which hæmorrhage occurred. He (Dr. Gordon) saw no later than on the day prior to this meeting a case of fever in which the enteric symptom prevailed, although there was no trace of what was termed a typhoid rash, and not a single spot or typhoid eruption on the body, but from the symptoms and temperature he looked upon it as a case of typhoid fever. It was a case in which there were great chest complications, and one which he supposed was rapidly passing into tuberculosis. There were some circumstances in connection with the case which made him predict that it was one in which there was likely to be hæmorrhage. Unfortunately, his prognosis was verified last night, for there was very alarming hæmorrhage of the bowels, which recurred two or three times, and left the patient very weak indeed. It was an example of hæmorrhage of the bowels coming on in the second or third week of a fever, which was not marked by an eruption of any kind whatever, but in which the symptoms were more prominently those of enteric fever than any other. One very important circumstance he wished Dr. Kennedy had gone into was the treatment of those cases. He (Dr. Gordon) had about twelve months ago a very alarming case of typhoid fever which he took great interest in. It occurred in a person 22 years of age, and there were accessions of hæmorrhage at intervals of about seven or eight days, a protracted fever, and then two further attacks of hæmorrhage. Death then seemed imminent. He thought the recovery that was brought about in that case was caused by stimulant, enough to keep life going, being given in the form of the subcutaneous injection of ergot. He thought it had most decidedly a marvellous effect. He was of opinion that turpentine produced irritability of the stomach, and therefore could not be adopted. In such cases he would strongly recommend the subcutaneous injection of ergot—five or six drops of the ergotine.

Dr. HENRY KENNEDY, in reply, said that he did not for one moment question the gravity of hæmorrhagic cases. Out of very nearly fifty cases the deaths were exactly one in four. They would often see rises and falls in temperature occur in cases in which there was no hæmorrhage. As regarded the question of treatment he could not advise anything. He had tried the ergotine internally but not subcutaneously, and he had not sufficient experience of the medicine to say it was a useful one. He had certainly seen benefit arise from the use of turpentine, the patient's strength being kept up by the ordinary means well known to members of the Society.

The business of the Society for this session then concluded.

Dr. PROTHEROE SMITH has been elected a Corresponding Member of the Medical Society of St. Petersburg.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 8, 1874.

### THE HARVEIAN ORATION, 1874.

Dr. WEST was the orator selected by the President for this year, and on the 27th ult. a good audience assembled at the Royal College of Physicians to hear the annual *éloge* of the discoverer of the circulation.

Dr. West acknowledged at the outset that he had, since being appointed to the office, perused all the preceding orations of which he could obtain a copy, not, as we can well understand, with a view of borrowing from them, but in the hope of meeting, particularly in the earlier ones, with something to assist him in an attempt to set before his audience the man Harvey "in his habit as he lived." The attempt is not unworthy of the office, and it was so far successful that those unfamiliar with the story of his life will peruse with pleasure Dr. West's lecture—which has already been published as a small volume—and those who know the story well may compare their estimate with that of one who has just studied so many Harveian orations.

We may confess with Dr. West that his study has not been rewarded by any discovery of value, and he has, therefore, not the opportunity that Professor Rolleston last year enjoyed of enriching the College Library. Nevertheless, the story of Harvey and his times is just what may be expected to form the staple of these productions, and the lessons of patriotism, loyalty, open-handed bounty, forgiveness of injury and detraction, deep religious feeling, and devotion to his profession taught in his life, can never be ill-timed at a College commemoration of Harvey.

From his earliest trophy—the diploma of M.D. from the then great University of Padua, which is now preserved in the College archives—to his last will and testament all that relates to Harvey is of permanent interest. From the latter may be gathered some notion of his tender affection. Brothers, sisters, nephews, nieces, are all remembered, and to each some token of love is bequeathed; but Dr. West thinks that nothing, even in this touching document, is so touching as his reference to a certain Will. Foulkes, whether related to him or not does not appear, who seems to have been a feeble-witted person, and under the care of one of Harvey's nieces. He left to her "all the linen, household stuff, and furniture at Coome, near Croydon, for the use of Will. Foulkes." Further on he assigns a stated

yearly sum towards his maintenance; and then, in the last sentence, as if he feared lest something, in spite of all his care, might yet befall one so helpless, he provides for his custody in the event of the death of his niece Mary Pratt. There are also bequests to the poor of Folkestone, to the poor of Christ's Hospital, to the poor children of his cousin; and then, "one hundred pounds among other my poorest kindred, to be distributed at the appointment of my executors." Then there come in touches of kind remembrance of old friends. "My little silver instruments of surgery to Dr. Scarborough, and my velvet gown. Five pounds to my loving friend Dr. Ent, to buy him a ring to keep or wear in remembrance of me;" and, in a codicil, he adds, "ten pounds to my good friend Mr. Thos. Hobbes, to buy something to keep in remembrance of me." It is strange to find evidence of close intimacy between two men so widely different as William Harvey and Thomas Hobbes. Dr. West suggests that their common acquaintance with Bacon brought them in contact, and Harvey's genial temper would attach him to a man who "was well-beloved for his pleasant facetiousness and suavity."

Harvey was five years at the King's School, Canterbury. He then went to the University, entering Caius College 31st May, 1593. He took his B.A. in 1597, and then went to Padua. At that time Padua had somewhat declined; but still it held a high place as a school of anatomy and medicine, and taking advantage of Harvey's sojourn there, the orator mentioned a number of interesting points in its history which he had gathered from Meiner, Cibrario, Tiraboschi, Monteil, Colle, Riccoboni, Facciolati, and others. There are other reasons besides Harvey's five years' stay that render these particulars interesting, and we may therefore avail ourselves of Dr. West's researches and furnish some of them to our readers:—

Padua was once a university with 18,000 students—a true republic of letters, and a republic of a most democratic kind. The professors, originally elected by the students, were in Harvey's time still nominated by the University. The different faculties were independent of each other as far as their internal government was concerned, and the ecclesiastical censures which afterwards troubled the life of Galileo did not interfere with his functions as Professor at Padua. Two professors were appointed on every subject, the one a foreigner, the other a citizen of Venice. These professorships were not mere titles of honour, but, in addition to the fees paid by the students, the different chairs were well endowed. Thus, in the year 1598, about the time when Harvey entered there, the annual stipend of the Professor of Practical Medicine was 1,000 florins, a sum equal to nearly £500 at the present day; and Fabricius himself, as Demonstrator of Anatomy, received 500 florins, or nearly £250, while as Professor of Anatomy and Surgery together he received more than double that sum.

Instead of 18,000, there were at the end of the sixteenth century not above 1,500 students; but, in spite of diminished numbers, the old reputation of the place survived, and its old traditions lingered still about it.

Dr. West said: "The old customs had not yet fallen into disuse in Harvey's time. The medical session began on October 18th, the day dedicated to St. Luke, the beloved physician, when all assembled in the church (the

bishops and chief clergy being invited) to hear an oration by some doctor or other learned person in praise of the study of medicine, and to urge the scholars to its diligent pursuit; the whole assembly then heard mass, after which the Litany of the Holy Ghost was said; for in those days people held, in profession at least, to the belief—"If any of you lack wisdom, let him ask of God, that giveth to all men liberally and upbraideth not, and it shall be given him."

To Harvey, no doubt, the great attraction of Padua was its anatomical school, which then presented opportunities for study greater than any other in Europe. Twice during the academical session, which extended from St. Luke's Day to the Feast of the Assumption, on August 15th, the whole human body was required to be publicly dissected by the Professor of Anatomy. Nor were the means neglected to ensure the fulfilment of this regulation; for it was provided that, if no criminals were executed within the province of Padua, the University should have the power of claiming bodies from Venice, or elsewhere within the Venetian States. Not seven years before Harvey came to Padua, the Venetian Government had built there at its own cost a new anatomical theatre, and had placed over its entrance an inscription commemorating the liberality, as well as the genius of Professor Fabricius, who had built the former theatre at his own expense. Between Fabricius and Harvey a fast friendship seems to have sprung up, or rather that loving relationship which is so beautiful between the youth scarce twenty and the old man of well nigh seventy years.

In his liberality and indifference to wealth Harvey may have followed the example of Fabricius, who contented himself with his stipend, and refused large fees. When grateful patients forced their gifts on his acceptance, he with quaint humour arranged them all in one large room, and wrote upon the door "*Lucri neglecti Lucrum*," which Dr. West rendered—"See what I get by saying No!"

The name of Fabricius is the first subscribed to Harvey's diploma. Next to it comes that of John Thomas Minadous, an accomplished and much-travelled man, the son and brother of physicians, and they of no mean repute. Next comes the name of Julius Casserius, a native of Piacenza, whom Fabricius took out of compassion as a poor boy to be his lackey. The lad showed parts; Fabricius taught and trained him, and so from valet he became pupil, from pupil friend, then colleague of Fabricius, and, last of all, his successor in the professorial chair. Servitor, Sizar, Tabarder—terms and conditions which we have now done away with in our universities—brought then no sense of inferiority, for all felt equal in their citizenship in the commonwealth of learning.

"Let these suffice," said the orator, "as samples of the men with whom Harvey was in daily intercourse. It would be easy enough, especially if one travelled beyond the somewhat narrow circle of those whose pursuits were exclusively connected with the profession of medicine, to swell the list of those remarkable alike for their genius and their culture, who were the inheritors of all that was most worth the possessing of that wonderful *renaissance*, that new birth of the world, out of which came alike the evil and the good of modern society."

Dr. West having glanced at the great period in which such giants in literature and science arose, passed on to the time when Harvey began practice, a time in his life of which we know little, and then turned his attention to the anatomical discoveries which fell thick upon the half century that culminated in Harvey's great work. Into these details it is not necessary for us to plunge, since they are all matters of medical history, though briefly and pleasantly repeated in the Harveian Oration for 1874.

### THE IRISH APOTHECARY QUESTION.

THE Irish Pharmacy Question may be said to be adjourned for a parliamentary year by the remission of Mr. George Errington's Apothecaries' Bill to a select committee; for although the committee, consisting of Mr. Errington, Sir Michael Hicks Beach, Sir John Gray, Mr. Corry, Dr. Cameron, Mr. Leslie, and Mr. Chaine, has been nominated, it is not certain that they will meet this session, no witnesses have been summoned, and it is hardly possible that they can—even if they sit this year—report to Parliament during its present session. No one, however, will regret the delay, if it be intended to institute a thorough inquiry into the subject; the more light is thrown upon the present position of the Irish Apothecaries' Company, the more certainly will the desired object—that of putting an end to the misuse of its legal powers, and placing the control of Pharmacy in Ireland in competent hands—be attained. No one, except the majority of the Directors of the hall, has anything to fear from investigation; and it is much better that the question should be settled by the House of Commons, in the interest of the public, than that it should be cobbled up by means of a compromise between druggists and apothecaries. We understand that the Irish Chemists' Association has a second time brought the Directors of the Hall to their terms, and that the *ordre du jour* is, for the present, cordiality and reciprocity; but we believe it may be conceded that, whatever settlement of the question be eventually attained, the proposed Bill of the Company, which is to adjust the matter in their own interests, is entirely delusive, and will never become law, either in this or any other Parliament. We have reason to know that there is a severe squall brewing in the Medical Council, which may add fresh difficulty to the already embarrassed position of the Company; meanwhile, the Amended Bill of the Irish Apothecaries' Company has made its appearance.

The proposition of the Company provides for the establishment of no less than three grades of pharmacists in Ireland—firstly, the licentiate apothecary now in existence under the Company's Act, who is required to pass through a curriculum and examination in medico-chirurgical subjects, and is supposed to be a medical practitioner as well as a dispenser; secondly, the pharmaceutical chemist, who shall pay £5 5s., shall pass only through a pharmaceutical and arts examination, and three years' apprenticeship, but shall be entitled to compound prescriptions; and, thirdly, the chemist and druggist, who shall pay £1 1s., and shall, if now in business, pass no examination, or, if not yet so employed, shall submit to a "modified examination," and

shall be entered on the list of chemists and druggists, but shall not compound prescriptions.

The pharmaceutical chemists so licensed are to be erected into an Irish Pharmaceutical Society, in whom is vested the election of a part of the examining board, and the "making of bye-laws and rules for the advancement of pharmacy and the good government of the society."

The examining board is ultimately to consist of four members of the Court of Examiners of the Apothecaries' Hall, and eight appointed by the Pharmaceutical Society, and, finally, the Bill imposes upon persons falsely assuming the titles or functions of registered chemists penalties similar to those declared by the Medical Act.

We think it right to give this sketch of the Bill, although it has not been introduced into Parliament, and may be looked upon as representing the desires of the Directors of the Hall rather than a serious proposal for the acceptance of Parliament. If the Bill ever arrives at the dignity of a parliamentary measure, it will need, and we believe receive, the firm opposition of every member of the medical profession and of the licentiate apothecaries themselves. In its present stage of development it is no more than a somewhat audacious incorporation of demands which could not for a moment be listened to either by the profession or the public.

### A NEW PROPOSAL FOR MEDICAL REFORM.

THOSE who are conversant with the proceedings of the General Medical Council will not fail to remember that Sir Dominic Corrigan, as representative of the Queen's University, is the uncompromising and immovable opponent of conjoint examination, but we have not hitherto been as explicitly informed as we could desire as to what alternative the learned baronet would propose. A proposition has, however, been very recently submitted by him to the College of Physicians in Ireland, which places his views beyond any doubt, and which, emanating from so representative a man, deserves, and has received, every respect and attention. Sir Dominic Corrigan's suggestions are in the form of a proposed Bill to amend the Medical Act, and are briefly as follows:—

1. That in future no person shall be registered without separate diplomas in *both medicine and surgery*.
2. That in future, though any person holding degrees or diplomas from a licensing body shall be entitled to practise, no person shall be allowed to hold any public appointment whatever unless he shall, in addition to his diploma examinations, have passed an examining board, which is to be called the Civil Medical Board, and in respect of so passing, he shall be entitled to add the letters C.M.B. to his titles in the register.
3. That this Civil Medical Board shall consist of seven examiners from each division of the kingdom, appointed by the Medical Council, but whether localised in London or peripatetic, the draft bill sayeth not.
4. That this Board shall have nothing whatever to do with curriculum, or methods of study, and that the fee for admission to its examination shall be £5.

We understand that Sir Dominic Corrigan's Bill was rejected by the College by a majority of six. The most superficial glance at its provisions is sufficient to indicate a

vital fault in its principle, in pointing out which we content ourselves for the present. It enunciates the principle that the degrees now conferred by licensing bodies are an insufficient guarantee of competency to hold a position in even the lowest grade of public medical service, and yet it permits any person to engage in the most extensive private practice, and to hold the office of Physician to Her Majesty the Queen, which Sir Dominic Corrigan himself occupies without the possession of that *imprimatur* which he declares to be necessary for the tenancy of a dispensary at Ballysloughgattery.

The *sequitur* is inevitable. If colleges be incompetent or venal, and abuse their privileges of admitting ignorant persons to the profession, they should be unhesitatingly superseded—if not—the function of Sir Dominic Corrigan's C.M.B. is evidently redundant.

### CHOLERA IN FRANCE IN 1854, 1855, AND 1865. (a)

#### III.

(Continued from page 535, vol. xvi.)

#### THE EPIDEMIC OF 1865.

TEN years elapsed after the epidemic of 1855, when in 1865, cholera for the fourth time made its irruption into Europe. On the three previous occasions it had advanced from the north-east; this time it invaded from the south, appearing first at Marseilles in the month of June. Immediately afterwards it extended to the valley of the Rhone; in August it had reached the Saône-et-Loire; in September the departments of the Seine, the Seine-et-Oise, la Drôme, l'Hérault, la Haute-Marne, Savoy, and les Pyrénées-Orientales. In October, in l'Allier, l'Eure-et-Loire, l'Oise, l'Aisne, la Seine-Inférieure, la Moselle, and the Pas de Calais. In November, l'Orne, la Manche, Tarn-et-Garonne, and the Vosges, disappearing in l'Allier, l'Hérault, l'Eure-et-Loire, and la Haute-Marne. In December it reached Finisterre and Calvados, still persisting in some of the departments invaded three months before; it prevailed with violence at Cherbourg during the three most severe months of winter. In the course of the following year, the disease, which elsewhere seemed to diminish, broke out afresh in Paris during the heat of summer, proving also very severe in Amiens in June and July, extending in the latter part of 1866 towards the north-east of France, and not finally disappearing till the end of 1867, after having invaded fewer departments and caused less mortality than the preceding epidemics. With the exception of its point of arrival and direction followed, this epidemic presented no points of difference from either of the preceding. The hot season was that in which, for the most part, the disease prevailed with greatest severity; this was especially the case at Marseilles and Toulon, while at Paris the first outbreak took place in October, 1865, with a recurrence of the affection in June and July 1866; its great intensity having also taken place at Amiens during the same two months. Cherbourg, however, was an exception, the epidemic having there been most severe in December. Unlike the epidemic of 1849, it seemed then to acquire an aliment suited for its development, proving that when the disease breaks out at that season it may prove as severe as during the hot, in which it usually occurs. As in previous epidemics, that of 1865 ravaged some places that on previous occasions had been exempt, or but slightly infected; thus, Amiens, with a population of 50,000 persons, which had only 165 deaths in 1854, lost 1,694 in 1866, of which number 1,416 in July. On the other hand, although the

communication between Lyons and Marseilles was constant, the ravages of the disease in the former during each of the epidemics was small. In 1849 the disease had been limited to the military hospital; in 1855 there were 525 deaths; in 1865 only about 100; in 1866 only 18, and no more than 50 attacked. The recurrence of the disease in Paris after being dormant during a period of six months seems to indicate that the germ of the disease may remain latent for a certain time, and then under favourable conditions become active, heat being the principal of them. With regard to the decrease in the numbers attacked in particular localities, Dr. Vinci, of Naples, finds explanation in the decrease in the numbers susceptible of attack, and he recommends that persons who had fled from infected localities, or strangers about to enter them, ought not to enter them until some days after the cessation of the disease. As in previous epidemics, premonitory diarrhoea, although not invariably present, was so very generally. According to M. Baudrimont, the albumen of the blood, transformed into *diascase* in cholera, was found in the alvine dejections mixed with a matter resembling beer yeast. The improved hygienic conditions of localities as compared with previous attacks seemed to diminish the number of cases in 1864, but the ratio of mortality was about equal to that in other epidemics; also that in some conditions, in Paris for example, mortality was great, although the number attacked was relatively few. With regard to the pretended immunity of certain professions, the epidemic of 1866, like those preceding, furnished negative or contradictory conclusions; thus, while according to some the inhalation of gas disengaged from oil had a preservative effect, Dr. Créquy shows that *employés* in gas manufactories enjoyed no special exemption from the disease.

With regard to the nature of the disease several reports indicate, as on previous occasions, its identity with paludal fevers; Dr. Poggioli considers the disease to consist in a deficiency of electricity in the body; but in these theories nothing has been adduced to support the conclusions arrived at, nor was anything scientifically new discovered as to the nature of this disease, which, according to the Committee, is not identical with any other but is altogether *sui generis*. As to the *genesis* of the affection no new theory was brought forward. The great majority of authors recognised India as the "home" of the disease, Dr. Balaguer referring its chief source to Hyderabad, and all tracing the epidemic of 1832 to its extension from Asia. In like manner, that of 1859 was attributed to the same "home;" and if that of 1853 seemed to be the recrudescence of germs only partly destroyed in some parts of the east and north of Europe, the epidemic of 1865 seems to have travelled by sea to France. In May, 1865, pilgrims from all points of Islam assembled at Mecca for the festival of Beiram. Until the arrival of those from India there was no cholera among them, but on their arrival it manifested itself and spread among them, placed as they were in the worst possible hygienic conditions. The pilgrims subsequently embarked at Djeddah, arriving thus at Suez, then at Alexandria, where cholera broke out on 11th June; on the 17th it extended to Aboukir, Tintah, and Cairo, seven days afterwards Rosetta, Damietta, and Mansourah. It appeared in Constantinople on the 28th of June, three days after the arrival of the ship *Moukberi-Surur* from Egypt, some persons on board suffering from diarrhoea having been sent to the marine hospital there, the cholera first appeared where they had disembarked. Shortly afterwards it appeared at Ancona, Barcelona, and Marseilles, extending thence from south to north, from Lyons to Paris. Thus, in following the advance of the disease from Mecca to Alexandria, seeing it soon after appear at Constantinople, then at the commercial capitals of Italy, Spain, and France, all of which have frequent relations with Alexandria, we see in this succession all the characters of a disease imported from India into Europe. Sicily, which refused to admit any suspected vessel, remaining exempt.

The greater number of reporters discuss the question of how the disease, once introduced into France, propagated itself. Some of them continued to maintain the opinion

(a) Rapport sur les Epidémies du Cholera Morbus qui ont régné en France pendant les Années 1854 et 1855. Par M. Barth. G. Masson, Paris, 1874.

of its spontaneous development under conditions unknown to them; but the majority believed in its extension from infected places, although, the Committee observes, it does not follow with the same degree of certitude that each new explosion of the disease should be from a fresh importation. As to the *agents* of importation and modes of transmission of the disease, it is found from the reports that these are not limited to people and their things, but include also other matters, and it is observed that during the epidemic of 1865, in Russia, the transmission of the disease by man was only observed in reference to two towns, namely, Odessa and Borch. According to Dr. Roch, cholera was imported in the Isthmus of Suez by its *foci* (foyers), and not by contagion properly so-called. These *foci*, transported by the pilgrims disembarking at Suez, or formed by them at Alexandria, spread along the fresh-water canal to Serapium, Ismalia, and to the threshold of El-Guisr, where it seemed to be arrested. In France, some authors of reports consider that the disease was not directly imported, and give instances, as at Raon-l'Étape, Vosges, Pontoise, Argentan, Orne, Mayenne, Montataire, and Oise. Dr. Bourguet in his report on the epidemic at Aix-en-Provence, considers that not only people and things, but also the air may convey cholera, as in the case of all other epidemics. He cites sixteen attacks in which no contact with other cholera patients could be traced, but many others clearly trace the direct conveyance by human agency of the disease from a contaminated to a healthy locality, so as to leave no doubt on the matter. Nor were there wanting evidences that persons may be the means of conveying the disease without themselves being subjects of it either at the time or subsequently, instances of this being cited in the reports; also that the germs of cholera being introduced into a locality the disease does not always break out in a fatal form, seeming to require for this purpose special conditions of an atmospheric or telluric character the precise nature of which it is difficult to determine. With regard to individuals who become attacked or remain free from the disease, this seems to depend upon conditions of strength, health, predisposition, and idiosyncrasy, permanent or transitory, the characters of which also remain unspecified. Cholera, like all other transmissible diseases, may therefore, when brought to a locality, be transmitted from an affected to a healthy person, but as with the locality, so the individual must have the morbid aptitude necessary to receive it.

As in previous epidemics, that of 1865 indicated that bad hygienic conditions of persons or localities conduced to the occurrence of cholera, Dr. Maurin, of Marseilles, being even of opinion that contagion only acts where these conditions are defective, and the dejections abandoned without being previously disinfected. The necessity of disinfecting the objects and habitations is indicated with greater force in the reports of the epidemic of 1865 than in those preceding, it being observed that under certain conditions both may retain the germs of the disease during a long time. Dr. Baldou reports an instance where those germs were thus retained active during one entire year in a room that had remained shut up without being cleaned or attended to subsequent to the occurrence in it of a death by cholera. The isolation of the affected was insisted upon whenever practicable, also the avoidance of crowding, and distribution of the sick in hospitals or buildings specially appropriated, although it is pointed out that it is seldom practicable to prepare in advance a sufficient number of the latter against an epidemic. All the writers agree that when the country is attacked it is impossible by means of sanitary cordons to preserve a locality from attack, although several point out the importance of subjecting to disinfection and other sanitary precautions the persons so arriving and all belonging to them. If possible, measures should be taken at the frontiers to prevent the introduction of the disease into the country, or, better still, to arrest it near its source by means of international measures of a sanitary nature. These measures ought to be taken against its introduction into Egypt, from which it has hitherto

been introduced into France. The greater number of medical men advocate rigorous quarantine measures, and some suggest that they should be more strict than they are, five days being, according to them, insufficient where communication takes place by sea. M. Languadin considers that the period of incubation of cholera extends to ten or even fifteen days, and that therefore the period of quarantine ought to be about twenty days. M. Bourguet, of Aix, having established that cholera may be transmitted to a distance, that the air becomes tainted by its germs and vitiated to a greater or less distance from its source, declares that sanitary cordons are powerless, that lazarets and quarantine establishments in towns, or at a little distance from ports of commerce, are of little use, and that to be effectual they ought to be situated some distance at sea. He proposes to establish sanitary medical officers at the principal cities in India and Asia where cholera is endemic, and as has indeed been done ever since 1864 in India. He instances the good results which have followed that measure in Egypt, Turkey, Syria, and other places where plague becomes spontaneously developed. Dr. Cazalas, on the other hand, declares measures of quarantine to be useless, that they are always taken too early or too late, these views being based upon his theory that cholera is engendered on the spot, and is not transmissible.

In the treatment of the disease the reports of the epidemic of 1865 confirm those of previous epidemics as to the importance of the early employment of remedies; the majority also believe that no one plan of treatment is applicable in all cases, but that different therapeutic means, even opposed to each other in appearance, may conduce to the same end, and meet the symptoms observed at the bed-side. It is also observed that the proportion of fatal cases in 1865 was as nearly as possible what it had been on previous occasions. Besides the remedies already mentioned, the following have been used, namely—Sulphuric lemonade, recommended by Dr. Worms, citrate of magnesia, bicarbonate of soda, subnitrate of bismuth, bichloride of mercury, sulphate of copper, arsenic, sulphate of quinine, aconite, the nitrites, spirit of camphor, ergotine, calabar bean, phenic acid, benzoic acid, benzoic ether, benzoised water, static electricity, pepsine, inspiration of oxygen and iodine, chlorine fumigations, mustard baths, painting the abdomen with castor-oil, the suppression of all drinks, injection of salt water into the subcutaneous tissues, injection of the defibrinated blood of animals, &c. All these, however, like the other remedies proposed, have proved failures in true cholera, although each in turn has been vaunted by its advocates.

## Notes on Current Topics.

### Laughter.

THE *Journal of Mental Science* reports that Dr. Ewald Hecker has made some ingenious observations on the physiology of laughter, which are recorded in the "Zeitschrift für Psychiatrie," xxix. Band, 6 Heft. Laughing may be produced in two ways, by tickling or by the presentation of a humorous idea to the mind. The application of a stimulus to the sensory nerves has been proved by Nothnagel and others to produce, through the agency of the sympathetic nerves, a contraction of the blood-vessels, and this condition is known to be accompanied by dilatation of the pupils. Dr. Hecker has found, by careful observation, that during the process of tickling there is a slight but decided intermittent dilatation of the pupils. This is best observed with young

people. Dr. Hecker, therefore, assumes that during tickling there is a contraction of the vessels and an increase of the tonicity of the vascular walls. There is thus a relaxation of the pressure of the vessels on the brain, and by the *vis a tergo* effect of the muscular movements which accompany laughing, the blood is drawn from the veins to the heart during inspiration, while during expiration the column of venous blood is arrested. This explains the swelling of the jugular veins and the reddening of the face during violent laughter.

The author, therefore, concludes that laughing is a reflex movement destined to counteract the intermittent relaxation of pressure on the brain, through an increase of pressure. The cause then of laughter seems to be a diminution of the pressure of the vessels on the brain through an increase of the tonicity of their coats. Dr. Hecker affirms that when a comical idea is presented to the mind causing laughter there is also a dilatation of the pupils.

I may here observe that there is another way by which laughter may be produced—viz., by forcibly pressing with both hands the arms and legs from the extremities upwards, so as to push the column of venous blood in the limbs towards the heart. As this is very likely accompanied by a lightening of the pressure of the venous current upon the brain, it may be a confirmation of Dr. Hecker's theory.

It appears from a notice in the "Centralblatt" (No. 10) that Dr. Hecker has published a pamphlet of eighty-three pages, upon the "Physiology and Psychology of Laughter and the Comic," Berlin, 1873, in which his studies on the subject are pursued.

#### "Inter-Hospital" Accommodation.

LORD ELIOT writes to the *Times* to suggest that when they close for repairs *special* hospitals should make some arrangement with *general* hospitals to receive their in-patients, or, if that cannot be done, that a fund should be raised for the purpose of enabling those who would otherwise be in-patients at special hospitals to obtain additional comfort in their own homes. His lordship looks upon the diet, rest, and other advantages of the hospitals as invaluable, and instances a case in which these were much praised by a patient of the Hospital for Epilepsy. Just now we may add St. George's Hospital is closed, so that generals and specials are in the same predicament.

#### The "Retrospect."

We are glad to welcome the 67th half-yearly volume of "Braithwaite's Retrospect," which is now the only work of the kind. The selections are made with great care, and the synopsis is becoming a very valuable feature.

#### Practice in Chili.

THE British Minister has made representations to the Chilean Government complaining that our English diplomas are not recognised there. A correspondent says that the examinations in Chili are conducted in Spanish, by a board of examiners who may find a rival in the new comer, and therefore do not wish to admit him. Hence it is argued that qualified Englishmen are refused leave

to practice, while quacks abound and do much mischief. The Chileans deny that English physicians are up to their standard. A good deal of gossip has taken place on this subject. Perhaps it would be only just to remember that we in England do not register Chilean diplomas. Some of us would also argue that Chilean physicians are not up to our standard. If a Chilean physician of the highest pretensions appeared at one of our boards he would be examined in English, and he would have some difficulty in being admitted as a candidate. Until he had achieved this the General Medical Council would not place his name on the register.

#### The College of Surgeons.

MESSRS. MARSHALL, HILTON, and BAKER succeeded at the election into the Council on Thursday last. Some two hundred and thirty Fellows voted, and the polling was prolonged till 5 p.m. The numbers for each candidate were as follows:—Mr. Marshall 152, Mr. Hilton 116, Mr. Baker 102, Mr. Smith 95, and Mr. Hussey 58. The numbers of "plumpers" for each candidate were—Mr. Marshall 13, Mr. Hilton 19, Mr. Baker 11, Mr. Smith 20, and Mr. Hussey 3.

#### International Medical Congress.

THE organisation of an International Medical Congress at Brussels, in 1875, is being carried out with great activity. The President is to be Dr. Vleminckx, President of the Academy of Medicine, who has already presided over other scientific congresses with tact and authority. The Belgian Government has promised its co-operation, but it belongs specially to the members of the medical profession to set their shoulders to the wheel in order to make the scheme work.

#### General Medical Council.

As the Council meets to-morrow (Thursday), it seems idle to prophesy, and really little interest has lately been evinced about its proceedings in professional circles. Conjoint schemes to examine there are none, and the remarks of the visitors of examinations are currently reported not to contain anything terrible.

#### Hospital Sunday.

It is not even yet certain that London has this year collected as much as last, and the only point of much interest relates to the distribution of the fund. It will seem to many that the metropolis has done very badly compared to the example set by the provincial towns. The difficulties of organisation are enormous, but they are nothing to the apathy of the mass of the population.

#### Therapeutic Use of Common Glue.

If we are to believe a correspondent of the *Scientific American*, an invaluable therapeutic agent for hermetically sealing of wounds is at hand in every workshop in the form of common glue. He says:—

"For the last twelve or fourteen years I have been employed in a shop where there are over three hundred men at work, and, as is the case in all shops of this kind, hardly a day passes but one or more of us cut or bruise our limbs. At first there were but few that found their

way to my department to have their wounds bound up ; but after a while it became generally known that a rag glued on a flesh wound was not only a speedy curative, but a formidable protection against further injury. I was soon obliged to keep a supply of rags on hand, to be ready for any emergency.

"A man was running a boring machine, the sleeve of his shirt caught in the auger, bringing his wrist in contact with the bit, tearing the flesh among the muscles in a frightful manner. He was conducted to my department and I washed the wound in warm water, and glued around it a cloth, which, when dry, shrunk into a rounded shape, holding the wound tight and firm. Once or twice a week, for three or four weeks, I dressed the wound afresh, until it was well.

#### Dr. Letheby's Successor.

At the last meeting of the Commissioners of Sewers, notice of the following motion was given :—

"That a special committee be appointed consisting of nine members, to inquire and report as to the legality of the late election of a medical officer and food analyst, with power to have any legal assistance they might deem necessary, and report to the next court."

#### The Naval Medical Service.

THE death of Sir Alexander Nisbet renders vacant a good-service pension and the Honorary Physiciancy to the Queen. Sir A. Nisbet became Inspector-General of Hospitals and Fleets in 1855, was awarded his pension in 1865, and knighted last year.

Sir Alexander Nisbet's death gives rise to a move in the list of inspectors-general. It is said Dr. Davidson or Dr. Salmon will probably retire. Deputy-Inspector Mason, at present in charge of the Naval Hospital at Malta, will thus get a step.

The vacant post of Honorary Physician to the Queen is likely to fall to Dr. Smart, C.B.

#### Drug Sophistication.

ANENT the adulteration question, those interested will find in the American *Druggist* for May last an editorial article on the frauds which are habitually perpetrated by the substitution of chicory and other matters for dandelion in the preparation of extract of taraxacum. The writer firmly believes "that four-fifths of the dandelion used in America of late years is chicory. This custom has prevailed because no harm has been known by it, and because no great objection has been made to it." He, moreover, roundly charges that this fraud is principally to be found in the extract of taraxacum which is imported into America from England, and says that "almost all the imported extract of taraxacum is made from the chicory intybus, and we once had an English manufacturer contend it was the true kind to use."

But neither is chicory the only adulterant of dandelion, nor is the extract of taraxacum the only extract in which the fraud is habitually perpetrated. The editor of the *Druggist* has recently received a specimen of so-called ext. tarax., which he thus describes : It is made in Vermont, from a residuum in the distillation of oil of fir. They put into the kettle in which this stuff is boiled down a few dandelion tops and roots as dug up in the fields, to give it a flavour, and it has a little of the odour of dandelion ex-

tract which has been burned ; by heating the balsamic odour is more developed. A prominent manufacturing house of Philadelphia has purchased 2,000 lbs. through their agent in New York at 14 to 20 cents. per lb., and their card rate for the same is \$2.00.

"This," says the editor, "is no new dodge. It is well known that all kinds of what are called *common extracts* are put upon the market from the east (i.e. from England), but we did not know before what constituted the base, although they have a tarry appearance. This is now fully explained. All such extracts are totally inert and unfit for use, and their consumption has been and is large, be it said to the discredit of many doctors, who buy them because they are cheap, and druggists sell them because they buy them at a low price and sell them for a large profit.

"We have not time before going to press to fully complete the comparative examination, but have proceeded far enough to determine definitely that it contains really none of the properties or characteristics of dandelion, and to state advisedly that it is one of the most outrageous impositions on the profession and public that we have had occasion to investigate and expose. How long such frauds will continue to be perpetrated depends entirely upon the medical profession, who by throwing the worthless stuff back on the hands of those who manufacture and sell it, at a loss to them, may by this means force them into a line of honesty and fair dealing."

We suppose we shall be told by the English drug trade journals that all this is "in the way of business," and that our purism is ridiculous and behind the age, and that extract of chicory and fir refuse is a proper and honest article of merchandise, because it cannot be shown to be poisonous. Our old-fashioned code of morality holds that the manufacturer who makes up such a preparation, and the druggist who sells it knowing it to be false and fraudulent, is neither more nor less than a swindler, and ought to be dealt with as such by all honest people.

#### The International Sanitary Conference.

THE International Sanitary Conference at Vienna has decided that only in India cholera is endemic, and its outbreaks in Europe are due to importation from there. Dr. Dickson stated at length the regulations of the Indian Government for the improvement of the sanitary condition of India.

The Conference has rejected the theory of Pettenkofer that cholera is transmitted by healthy persons as well as patients. They agreed that living animals and foods could convey infection.

#### The Nursing Question.

WHILE the meeting promoted by the Order of St. John, and commented on in our last, was being held, another took place at Grosvenor House, for the purpose of establishing an annuity fund for trained nurses. This is not in any wise in rivalry to the more ambitious scheme, and it was intimated that it might even amalgamate. Not too soon, we hope, for it is quite possible that it would be wiser to keep the annuity fund separate, and let it apply to all nurses, whether in the St. John's Society or not. The Duke of Westminster, Baron de Worms, Professor Erichsen, and Mr. Brudenell Carter moved the resolutions,

and subscriptions and donations to a considerable amount were announced—£70 of the former and more than ten times as much of the latter. This is a good beginning, and a well managed fund may be the result.

### London Hospital.

THE new wing long talked of will soon be a reality. The foundation-stone has been laid, and the workmen are busy upon the building. This will give the hospital, when complete, 800 beds. As the Grocers' Company gave £20,000 towards the fund required, it is to be named after them. As announced last year, £100,000 was needed. About £94,000 has been raised. Will not some one with a fund to spare send a further £5,000? The Committee would be greatly relieved if £10,000 were sent. The money could not be presented to a better institution.

### Indian Medical Service.

As we announced, Surgeon-General Gordon, C.B., will leave Aldershot, to which he lately went, for India. He will go to Madras, to take the chief office of the Presidency.

Surgeon-General Currie, C.B., leaves Madras for Simla, in order to take the place of the late Surgeon-General Beatson.

Probably Deputy Surgeon-General Bent will, as senior, step into the full rank, and it is rumoured that possibly some further movements may be effected by the probable retirement of one, if not two officers.

### King's College Hospital.

DR. FERRIER is a candidate for the Physiciancy to King's College Hospital. For the Professorship of Materia Medica in the College, Dr. Burney Yeo, who has lectured on the subject in the College, and Dr. Milner Fothergill—a paper from whose pen lately appeared in our columns—are declared candidates. It is rumoured, too, that a third candidate may be induced to come forward in the person of Dr. Handsel Griffiths, whose works on materia medica and therapeutics are well known to all our readers, and who is a favourite teacher.

### The late Mr. T. J. Baker.

MR. T. J. BAKER, M.R.C.S., has fallen a victim to a mistake. He went at night to fetch a bottle from his surgery, and took up the wrong, containing carbolic acid. He took a dose before discovering his mistake, and vomited immediately. Nevertheless, he died in a very short time.

Mr. Baker was in this case the victim of his own mistake; but the accident serves to illustrate the dangers of such poisons as carbolic acid being found everywhere in such bottles as are usually employed for dispensing mixtures.

### New Books of the Month.

Johnson (Rev. S. J.), Eclipses, Past and Future; with General Hints for Observing the Heavens. 4s.

Orme, An Introduction to the Science of Heat. 3rd ed. 3s. 6d.

Symons (G. J.), British Rainfall, 1873; or, the Distribution of Rain over the British Isles during the Year 1873 as observed at about 1,700 Stations in Great Britain and Ireland. 5s.

Wanklyn and Chapman, Water Analysis. 3rd ed. 5s.

### University of London.

THE Senate on Wednesday adopted, by seventeen votes to ten, the following amendment on a proposal to obtain a new charter enabling the University to confer degrees on women: "That the Senate is desirous to extend the scope of the educational advantages now offered to women, but it is not prepared to apply for a new charter to admit women to its degrees."

### The Hunterian Museum.

THE Royal College of Surgeons of England has just presented the profession with the annual report of Professor Flower, their conservator. The plate of the collection is very creditable, and many valuable additions have been made during the year.

The pathological, osteological, and physiological collections have been largely added to during the year; but we have not space for details this week. There have been many additions to the collection of instruments. This department, it will be remembered, was originated by Sir William Fergusson, and amongst the donors are Messrs. Wormald, Prescott Hewett, Jabez Hogg, T. L. Hussey,

G. L. Wood, T. M. Stone, T. Carr Jackson, H. Bellott, and W. H. B. Winchester. The Fellows and visitors crowded the Museum during the exhibition for the purpose of examining the additions, in which they appeared to take great interest.

DR. J. FAYRER, C.S.I., has been appointed Physician to H.R.H., the Duke of Edinburgh.

ON Thursday last, the deed was signed by Mr. Albert Grant transferring Leicester Square to the Metropolitan Board, and the garden was thrown open to the public.

AGAIN there is talk of cheap gas being possible. The Board of Works has resolved that its duty is to protect consumers. Good as well as cheap gas is wanted.

IN the House of Commons last week, in Committee on the Valuation of Property Bill, Mr. Russell Gurney proposed a new clause exempting hospitals and infirmaries from rating. The clause was rejected by 162 against 41.

THE following offices are now vacant in King's College, London: The Chair of Materia Medica, the Chair of Comparative Anatomy, and the Physicianship of King's College Hospital.

THE Dean of the Westminster Medical School has contradicted the report that the Council would arrange for female students to be received. A proposal of the kind was made, but declined by the Council of the School.

AT Durham University College of Medicine and Physical Science a Chair of Biology is to be instituted in conjunction with Physiology. Salary to be £450 per annum, supplemented by a part of the fees. The duties of the Professor will begin next October.

THE income tax has been discussed in Parliament, but there is at present little hope that the odious impost will be abolished. Professional men find it peculiarly oppressive, and they, in this respect, lost much when Mr. Gladstone's proposal was not accepted by the country.

SLAVERY has again been brought up in reference to the Gold Coast, but Mr. Disraeli is not prepared for immediate emancipation, which he thought "would be an act of violence." This from the Premier in Great Britain! Shade of Wilberforce forgive. A million would suffice for compensation now. Five may not suffice in as many years.

MISS JEX-BLAKE has only herself to thank for the public declaration of her examiners that they "unanimously agreed that the answers were extremely defective on every subject." Such a letter would never have been sent to the *Times* had not Miss Jex-Blake first written one casting such serious imputations on the examiners that for the sake of their own honour and that of the University they were driven to resort to such a course, and that we believe for the first time in the history of the University of Edinburgh.

THE Council of Owen's College, Manchester, announce their intention of appointing previous to the commencement of the next winter session, a Professor of Anatomy in connection with the Medical Department of the College (with which is now incorporated the Manchester Royal School of Medicine, founded in 1824), and the Council guarantee for a certain term that the emoluments shall not be less than £500 per annum.

THE Pharmaceutical Society of England has not only challenged the accuracy of the latest additions and emendations in the British Pharmacopœia, but seems to consider, and, we think, with good reason, that it ought to be consulted in the compilation of so important a national work. The Council of the Society has accordingly resolved—

"That this Council respectfully urges upon the General Medical Council the desirability of associating more practical pharmacists with any committee which may be appointed for the purpose of preparing any future edition of the British Pharmacopœia, or any further addendum to the present issue. This Council would be prepared to nominate such pharmacists in the event of the Medical Council agreeing to their proposal."

"That a copy of the resolution just agreed to be forwarded to the General Medical Council with the respectful compliments of the Council of the Pharmaceutical Society."

Without entertaining or expressing the least want of confidence in the committee to whom the compilation of the Pharmacopœia was entrusted, we believe that the merits of the work as a practical standard of pharmacy would be enhanced if that committee were afforded the aid of the experience and research of some of the leading pharmacutists. We bear willing witness to the scientific treatment which their speciality receives at the hands of many members of the Pharmaceutical Society whose investigations and writings on chemistry and materia medica are in many instances quite up to the level of the best efforts of our own profession.

## Literature.

### CARPENTER'S MENTAL PHYSIOLOGY. (a)

THIS work is founded on the chapter on the "Functions of the Cerebrum" contained in the fourth edition of the author's "Human Physiology." In one sense it may be called an expansion of that chapter, and as pupils of Dr. Carpenter, we approach the work with unusual expectation. To say we are not disappointed might appear slight praise, perhaps, in the estimation of some, but as disciples of the author we could scarcely say anything more indicative of the highest standard of merit.

Dr. Carpenter unquestionably possesses the needful qualifications for such a task as he has imposed on himself, and his pupils and admirers in all parts of the world will be delighted to learn that he has accomplished it. The chapter on "Mental Physiology" in the early edition of his large volume, which formed our text-book, while as full as it well could be in that place, always left the

(a) "Principles of Mental Physiology, with their Applications to the Training and Discipline of the Mind and the Study of its Morbid Conditions." By Wm. B. Carpenter, M.D., LL.D., F.R.S., &c., pp. 787. London: H. S. King & Co. 1874.

impression that more would be acceptable, and now we have abundantly more—the full fruit of long research and patient thought.

The book is a complete repertory of facts, and these are all arranged with the utmost care. Illustrations meet us at every turn; but every one is in its place. The author evidently knew exactly the scope of his intentions when he sat down to give form to the work which had manifestly occupied his mind for years. There is thus a completeness about the treatise which is rare in these days of hasty book-making. With the subject always more or less on his mind, we can imagine the author, as opportunity offered, thinking over its various parts and digesting the mass of information he could bring to bear on each, until, every one being perfected, he had but to sit down and combine them into one, just as a great architect, intent on planning such a building as should worthily serve for the temple of justice we are promised some day to have, would not begin to sketch his plan until he had fully grasped in his own mind the shape and size of every chamber required and the other details essential to the design. But once having familiarised his mind with all the essentials of his building, he would then so arrange as to include all, utilising every available space and wasting none.

Dr. Carpenter, in finishing his long labour, that is, in giving form and consistency to his multifarious materials, has thrown over his work an extra charm, for he has clothed the whole in a captivating style that might make the success of a novelist. We cannot better illustrate the interest of both matter and manner than by revealing the fact that we have not yet been able to finish reading the work, because a couple of youngsters of the household have found out its charms and claimed leave in holiday time to read "that jolly book."

#### MEDICAL JURISPRUDENCE. (a)

MEDICAL JURISPRUDENCE, as a science, has of late years made such vast strides that works thereon, which were originally suitable as "text-books," have, in successive editions, assumed such proportions, that they now more resemble encyclopædic works of reference. The busy practitioner can ill spare the time to labour through a voluminous chapter relative to a case on which he may be called to give evidence, and still less can the student, already overburdened with reading, devote his time to the perusal of these ponderous volumes. It is to be regretted that jurisprudence is not cultivated by medical men more extensively than it is, and that in our schools it is not taught more thoroughly. It is only as a witness in a medico-legal case that the medical man comes prominently before the public, and, certainly, in some instances, the honour of the profession has been imperilled by the incompetency of the witness.

The publication of Dr. Husband's little book will, we believe, further the study of forensic medicine by students. The arrangement of the matter is simple, concise, and accurate, and with this book within their reach students should now have no excuse for neglecting one of the most important branches of their professional education. We cannot go the length of saying that the book is faultless, for we have detected errors both of omission and commission, for instance, we find no mention of oil of turpentine as an antidote to poisoning by phosphorus—a most successful mode of treatment, originated by Andant. On the whole, however, the faults are few and trivial, and we anticipate for the work a hearty welcome both by students and practitioners.

W. H. G.

## Correspondence.

### THE PATHOLOGY OF THE ARTERIES IN BRIGHT'S DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Milner Fothergill takes exception to certain statements in my last lecture on Bright's disease, which appeared in your columns. I think he has signally failed to convict me of inaccurate statements, as your readers may judge for themselves.

I properly alleged that thickening, or *hypertrophy* of the blood-vessels, was described by Rayer, Bright, and succeeding writers. This is not disputed; but Dr. Fothergill claims for Dr. Johnson the "discovery" of hypertrophy of the muscular walls of the arterioles!

As it is not apparent from the writings of the authors referred to that their statements related to lardaceous degeneration, will Dr. Fothergill kindly enlighten both myself and your readers as to what portion of the vascular structure which I have translated thickening, or what might with equal propriety be termed hypertrophy, it has reference?

The "next inaccuracy," which Dr. Milner Fothergill is pleased to term "a curious mis-statement," had better be quoted entirely, and not in the partial manner in which my critic has seen fit to do:—

"Dr. Johnson has ascribed the hypertrophy of the left ventricle to obstruction to the renal circulation, the heart thus acting against an obstacle and enlarging in consequence—what has been called a stop-cock action; but the explanation seems to me to carry its own refutation on the face of it."

I contend, Dr. Fothergill's opinion notwithstanding, that this is correctly expressed, and that if language has any significance, I have not misinterpreted Dr. Johnson's views, though possibly my own meaning, in the last portion of the clause, might have been more fully expressed. I apprehend, as most others do, I believe, that Dr. Johnson's contention is that the abnormal condition of the blood causes spasm of the minute arterioles of the kidney, obstruction to the flow of blood, increased vascular tension, and consequent hypertrophy of the muscular tissue of the arteries, and of the left ventricle of the heart. If this be so, as Dr. Fothergill himself states, wherein consists my "curious mis-statement?" My idea is, admitting and believing as I do that the altered condition of the blood occasions arterial tension, that this is *not* peculiar to the kidney, but *affects the entire vascular system*.

But the belief that there is simply spasm of the renal arterioles and consequent hypertrophy of the left ventricle, is no less an hypothesis than is Dr. Fothergill's manner of manipulating the theory amusing.

After referring to Traube's views, for what reason I fail to see, Dr. Fothergill remarks: "He (Traube) now holds that the obstruction caused by the hypertrophy of the muscular walls of the systemic arterioles is the chief factor (in the production of the hypertrophy of the left ventricle), the view always held by Dr. Johnson."

Here the pathological sequence is *exactly reversed*. As I understand Dr. Johnson's views, it is the tension and obstruction which cause the hypertrophy, not the hypertrophy the obstruction.

I rather fear that Dr. Johnson cannot be congratulated on Dr. Milner Fothergill's defence of his opinions, and my "curious mis-statements" must have more foundation in fact, if, hereafter, I am to take the trouble of noticing them as I now do.

I am, faithfully yours,

CAMPBELL BLACK, M.D.

Glasgow, July 2, 1874.

### DUGONG OIL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The difficulty of obtaining this oil at a reasonable price is now overcome. I am happy to tell you and my medical brethren that Messrs. Bell, chemists, 338 Oxford Street, can supply it at a price within the reach of all. The value of the oil in the treatment of phthisis pulmonalis is fully acknowledged by every physician who has prescribed it on my recom-

mentation for years past. The paucity of supply and high price has hitherto prevented publicity being given to this most valuable remedy for various diseases depending on constitutional debility. One important fact regarding the dugong oil I beg to recall to the memory of the profession is—the oil is not nauseous, never repeats on the stomach, keeps good for years, and can be taken by the most delicate, rapidly increasing the weight of persons labouring under wasting disease, and in cases of decline or scrofula a healthy aspect of countenance is quickly assumed. Any further information for members of the profession required of me will be readily answered by

Your obedient servant,

J. McGRIGOR CROFT,

M.D., M.R.C.P. Lond.  
Mandarin Hall,  
15 Abbey Road, St. John's Wood, N.W.

### CONVERSAZIONE AT THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE conversazione given on Wednesday evening last by the President and Fellows was very numerously attended by nearly all the leading members of the profession, as well as by a number of distinguished visitors, among whom we noticed the Earl of Harrowby, Sir Philip Grey Egerton, M.P., Sir Thomas Watson, Bart., the Right Hon. Peter Erle, Mr. W. Forsyth, Q.C., M.P., Mr. Montagu Chambers, Mr. Spencer Walpole, Mr. F. B. Curling, F.R.S. (President of the Royal College of Surgeons), the Master of the Goldsmiths' Company, W. Bowman, F.R.S., and many others. The visitors on arrival were presented to the President, Sir George Burrows, Bart., M.D., and then passed on to the various apartments, in which were placed a large collection of objects of interest for inspection, which included specimens of art pottery from Messrs. Minton's, a drawing of Leicester Square as it is, and many valuable oil paintings, lent by Mr. Albert Grant, a large collection of photographs lent by Fradelle and Marshall, the London Stereoscopic Company, and Barraud and Ferrard, microscopes of all kinds, and anatomical objects from all the leading makers, *cum multis aliis*. The cynosure of the evening, however, was a cast of the left humerus of Dr. Livingstone, showing the false joint consequent on the bite of a lion, whereby the body was identified by Sir William Fergusson. The visitors began to arrive at nine, and did not disperse until a late hour.

### SHORT SIGHT AND COMPULSORY EDUCATION.

LORD MONTEAGLE interpellated the Duke of Richmond last week as to whether his attention had been called to the effect of school life in developing short sight, and whether anything could be done to avert the evil. He stated that short sight was very likely to be developed by study in schools unless precautions were taken to prevent such a result. Statistics on this subject showed that of 10,000 children examined, 1,004, or 10 per cent., were short-sighted; and of that number only ten had inherited the defect or acquired it from disease. But with the stimulus which had now been given to education, and the prospect of compulsory attendance, there was danger that the evil would spread. He hoped the Education Department would encourage the use of improved furniture in schools to prevent straining of the eyes of the scholars.

The Duke of Richmond, said if the noble lord would communicate to the department the information he possessed on this subject it should be carefully read, and the desks which he suggested as of a better construction than those

in use should be inspected, if they were placed in the Education Department at South Kensington; but at the same time he must point out that it would be rather late in the day, when the country had been supplied with schools, in which had been placed these forms and desks which the noble lord said were improperly made, to insist upon their changing all their furniture.

Lord Monteaale is certainly justified in his anticipation that myopia will increase *pari passu* with universality of education, and it would be quite possible to mitigate the extent of this result by the use of well-adapted desks in well-lighted school-rooms. We do not, however, at all believe that short-sightedness is usually the effect of errors of position of the student, and we doubt that it is in the power of the educational authorities to influence materially the prevalence of that fault of accommodation. Myopia, where it is not congenital, is in fact one of the penalties of excessive use of the eyes by delicate, half-nourished persons, and its occurrence in a certain percentage of instances is quite inevitable.

It may be true that an insignificant degree of short-sightedness can be detected in as many as ten per cent. of all children examined, but we do not believe that it exists to a noticeable or inconvenient extent in one-fifth of that number, and, therefore, although we would not discourage the adoption of all possible precautions against its occurrence, we believe that the alarm sounded by Lord Monteaale is delusive.

### THE SILENT SISTER.

It would seem that the reproach of being either less active in research or less disposed to communicate to others the result of their labours, which is frequently cast upon Irishmen, is not without good foundation, for the fact is observed upon in the *Bookseller* of this month.

Referring to a recently published list of works, which includes no less than 114 catalogues and extends to 3,200 pages, the editor says:—

"In looking through the volume one is struck by the conspicuous absence of activity on the part of publishers in one part of the British dominions—Ireland. One solitary catalogue of eight pages representing Dublin, and one page from Belfast, are all that Ireland contributes; while from Scotland, and Scottish publishers in London, the lists are very considerable."

Editors and reviewers are profoundly conscious that a multitude of works which go to swell the list of London publications would be better unwritten, as they are unread. Nevertheless, a treatment such as the above is deplorably illustrative of the want of enterprise of Irish publishers, or the aridity of the literary soil of Ireland.

Irish medical books are usually good books, and our regret is therefore greater that so small inducements are held out to authors by Irish publishers, and that medical publishers find so little response from the constituency with whom they have to deal.

### Medical News.

University of Durham.—At a convocation held on June 23rd the following degrees and licences in medicine were conferred, after examination, at the Newcastle College of Medicine on June 15th, 16th, 17th, and 18th:—M.D.: George Rowell, M.B., M.R.C.S. M.B.: W. T. Wilson, Licentiate

in Medicine. M.R.C.S.; Ralph Young, Licentiate in Medicine, M.R.C.S. *Licences in Medicine*: Andrew Arnold; Charles W. Wilson.

**Small-pox Patients on Railways.**—At the meeting of the Metropolitan Asylum Board on Saturday, Dr. Brewer presiding, a letter was read from the Local Government Board as to the case of the girl Fox, who was sent from Hastings to London, and thence on to Willesden by railway, suffering from small-pox, to which their attention had been called by the managers with a view to their prosecuting the parties who had sent her, stating that they did not see that the law had been infringed by any person but Mary Fox herself. This communication was considered most unsatisfactory, and a resolution was adopted to write again to the Local Government Board, and state "that it is the opinion of the managers the case of Mary Fox is of such importance as to require in the interest of the public further investigation." We quite approve of this resolution.

## Gleanings.

### Cases of Grave Disease Caused by the Swallowing of Foreign Bodies.

BY DR. RAYSS.

I.—A BOY, *æt.* 5, swallowed, in Feb., 1841, while playing, a silver coin of the size of a quarter of a dollar. Neither emetics nor purgatives brought the money to light. But the boy lost his temper, and became lazy and morose. He did not cough or complain of pain. In October of the same year, after dinner, he went to sleep; suddenly he vomited, and the coin rolled along the ground, bright and light. After this the boy gradually recovered.

II.—A school-teacher, *æt.* 33, asked, on account of phthisis, for advice in the summer of 1842. He had in vain consulted several physicians, had become thinner and thinner, and coughed constantly. His expectorations were of a yellowish-green colour, and of a very bad odour. His lungs contained slime, his epigastric region was painful, and his stomach could bear only liquids. He mentioned that his sufferings had commenced, in his opinion, about two years previous. He swallowed by accident, while taking his dinner, a rind of pork. Considering his stomach as the cause of his sufferings, the doctor ordered an emetic. A roll, as long as a finger, and enveloped in mucus, was vomited, and proved by closer examination to be a piece of rind. A few days afterwards his appetite became better, cough, expectoration, and pain in the epigastric region ceased, and he became vigorous again.

III.—In October, 1857, the doctor was called to a man who suffered for a considerable time from fever and cough, and expectorated very bad-smelling matter. His lungs were filled with slime, the epigastric region was swollen and painful, and the tongue thickly coated and yellow. While eating, September, 1856, he had swallowed a hard body, and felt pain in the throat and back afterwards. An emetic was ordered. He vomited mucus and bile. After this the state of his health improved so far that he could pursue his business a fortnight afterwards. He then travelled on foot for several hours, felt unwell, with pain in his chest, and vomited at last a rough bone, one inch long, and of a very bad smell. Since then he has recovered entirely from his cough, his strength has increased, and he is quite well now.

Had the related cases terminated fatally, the pathologist would not, at least in the two last cases, have considered the roll of rind or the piece of bone as the cause of death. And yet to these was due the impaired health, as after their removal health became restored.—*Virchow's Archiv., Detroit Review.*

### Formation of True Bone in Penis.

BY DR. J. VON LENHOSSEK, Pest.

THE occurrence of *true ossification* in the penis has not been proved till now; the doctor's case is, therefore, very interesting, the more so, as not simple bony plates, but a larger piece of bone, besides a cartilaginous body, were found post mortem in a corpse, of which he only learned that the individual died from typhus, at 42. Both the car-

tilaginous and the bony formations were situated in the cavernous bodies. There was a dorsal bone, with a channel for the dorsal vessels, and three ventral bones, with channel for the urethra. They originated from the middle fibrous septum of the cavernous bodies; their colour was yellowish. The microscopic examination revealed three different layers in the bony substance. The external layer consisted of connective tissue and some elastic fibres; the middle layer was composed of the same elements, containing spindle-shaped cells; the inner layer was characterised by the *Haversian canals*, about which were grouped, in concentric lines, the bony canals, connecting with the larger cavities of the bone. The cartilaginous body originated, likewise, from the middle septum, had a white colour, and consisted of connective tissue and many elastic fibres. As the place of the erectile tissue was partly taken by the new formations, erections, of course, were very much interfered with. At last, the doctor states, that Prof. von Siegmund observed bony bodies in the penis, but only in life. In nearly all these cases the patients were, or had been, syphilitic. The seat of these formations was also the cavernous bodies of the penis. The professor considered them as complete ossifications of the lymph vessels.—*Virchow's Archiv., Detroit Review.*

### THE MEDICAL COUNCIL.

WE understand that at the meeting of the Council, to be held to-morrow, several questions affecting the *status* of certain members of the profession and of professional etiquette will be brought forward, and the Report on Professional Education further considered.

Notices of motion have been given for the appointment of a committee to prepare a new edition of the British Pharmacopœia, for the discontinuance of the publication of lists of registered medical students, and a draft of a proposed Bill prepared by Sir Dominic Corrigan, to amend the Medical Act of 1858, will be brought forward for consideration.

### NOTICES TO CORRESPONDENTS.

#### SPECIAL NOTICE.

THE Publisher will be glad to receive arrears of subscription for last and previous years. He regrets to state that there are still several gentlemen against whose names there are as many as four and five years' arrears standing, and who have had repeated applications for payment by letter made to them without any response. He thinks such should not be the case in an honourable profession.

#### CARMICHAEL PRIZES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Can you or any of your readers tell us why the Carmichael Prizes awarded to Drs. Ash and Dale have not been published and circulated as directed by the will of the late Mr. Carmichael?—"700 of the prize essays to be published and sent to all Cabinet Ministers and Privy Councillors in both countries, and to all councillors and governing members of all medical colleges and corporations." Surely, Sir, at this important crisis in medical politics the omission of such an enactment is highly culpable!

Yours obligingly,

EDWARDS CRISP, M.D.

29 Beaufort Street, Chelsea.  
July 2nd, 1874.

[The publication of the essays has been ordered by the Council of the Royal College of Surgeons in Ireland long since, and the delay is with the printer. We are informed that the essays will appear shortly.—Ed.]

DR. CAMPBELL BLACK's corrected proof of lecture on "Bright's Disease" did not arrive until Tuesday, when we were at press. It is therefore left over for our next.

ERRATUM.—The heading of Dr. Austin's letter of last week should have been "Estimation of Total Nitrogen in Urine," not in Urea, as erroneously stated.

MR. L. C. VENABLE is thanked.

MR. G. G.—If possible in our next.

DR. H. A. BROWN should write to the publishers.

HARLEY STREET.—We understand that the poor fellow is now in an asylum.

H. E. R.—The estimate formed of your neighbour from his recent actions is probably not far wrong. We advise you to restrain your just anger; he will poison himself with the alime from his own tongue some day.

**HOSPITAL CASES.**—Every surgeon of a hospital knows too well to what inconceivable meanness people will stoop to obtain medical advice for nothing. There might be some excuse in the prevalent opinion that the most eminent men are selected to see patients at special and other institutions; but the same practitioners can be consulted at their own homes—and, as a matter of fact, the well-to-do impostors who obtain gratuitous relief are not grateful enough even to send a donation to the institution. Shall I ever forget meeting, at an assembly at the Mansion House, the wife and daughters of an alderman, who had come to me disguised in shabby apparel to seek advice at a hospital where I had recently been appointed surgeon!—From *Cassell's Magazine* for July.

**DR. J. L.**—Decidedly a breach of professional etiquette, for which an apology is due to you. You may communicate our opinions to the gentleman concerned.

**DR. WILLIAMS.**—The Harveian oration by Dr. West at the Royal College of Physicians can be had in pamphlet form. It was delivered from notes, of which a printed and bound copy was sent us not many hours afterwards.

**BIOLOGY.**—A professorship on this subject will be established in the University Colleges of Medicine and Physical Science, Newcastle-on-Tyne, in October next. The stipend offered to candidates for the appointment is £450, with part of the fees attaching thereto.

**MALVERN COLLEGE.**—In the list of successful candidates for the East India Civil Service, Mr. H. S. Barnes, who was at the head of the list distanced his next competitor by nearly 400 marks. We are requested to state that the gentleman who gained this distinction was educated at Malvern College.

**COMMUNICATIONS, Enclosures, &c.**, have been received from Dr. Edwards Crisp, Chelsea. Dr. McGrigor Croft, St. John's Wood. Dr. Chapman, London. Dr. Heywood Smith, London. Dr. H. W. Williams, Fulham. Dr. F. H. Hamilton, New York. Dr. Marsden, London. Dr. Milner Fothergill, London. Dr. Waring Curran, Mansfield. Mr. King, London. Dr. Newman, New York. Dr. W. Haynie, Batesville, America. Mr. Charles Lunn, Edgbaston. Mr. Custance, Hospital Sunday Fund. Dr. Esler, Belfast. Mr. Venables, Hampstead. Dr. Frotheroe Smith, London. Dr. West, London. Mr. Aston, Wadingham. Dr. Chalmers, Caistor. Dr. Drysdale, Liverpool. Dr. Campbell Black, Glasgow. Dr. Julius Althaus, London. Dr. Lopez, Madrid. H. E. R. Dr. J. L. Dr. Williams. Mr. E. Gallais, London. Dr. Brown, Boston. Dr. Wyse, Dublin. Mr. George Gaskoin, London. Dr. Meadowscroft, Great Bentley. Mr. Wilkins Williams, London. Dr. Brinton, Philadelphia. Dr. Feber, Malvern. Mr. W. Berry, Manchester. Mr. W. Johnson Smith, Greenwich. Mr. J. Needham, London Hospital. Surgeon-General Gordon, Aldershot. Dr. Morgan, Dublin. Dr. Ormsby, Dublin. Mr. George, Battralough. Mr. Rivington, London. Dr. Drysdale, London. Dr. Aquila Smith, Dublin. Mr. Kennedybell, Oxford. Mr. Geere, Brighton. Mr. May, London.

#### BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

A Treatise on Pharmacy, designed as a Text-Book for Students and as a Guide for Students. Fourth Edition. By Edward Parish, M.D. London: Baillière, Tindall, and Cox.

Dr. Pereira's Elements of Materia Medica and Therapeutics. Edited by Messrs. Bentley and Redwood. London: Longmans, Green, and Co. On Diseases of the Heart. By T. Shapter, M.D. London: J. and A. Churchill.

On the Genito-Urinary Organs, including Syphilis. By W. H. Van Buren. London: J. and A. Churchill.

Hints on Ophthalmic Out-patient Practice. By C. Higgins, M.R.C.S. The Muscles of the Human Body. By Messrs. Manning and Elliott. London: H. K. Lewis.

Braithwaite's Retrospect of Medicine. Vol. LXIX. London: Simpkin, Marshall, and Co.

The Harveian Oration for 1874. By C. West, M.D. London: Longmans.

Report of the Autopsy of the Siamese Twins. Philadelphia: Lipincott and Co.

Thomson's Conspectus. Edited by Dr. Birkett. Longmans and Co. Suggestions and Reasons for Improving the Medical Branch of the Navy.

Report on the Sanitary Condition of Birkenhead. By Francis Vacher. Canada Lancet. Boston Medical Journal. Canada Medical Journal. Journal Thérapeutique. Courrier Médical. Le Progrès Médical. Hardwicke's Science Gossip. Monthly Microscopical Journal. The Obstetrical Journal of Great Britain. The Journal of Mental Science. Philadelphia Medical Reporter. La France Médicale, &c., &c.

#### VACANCIES.

Westminster Hospital. House Surgeon, without salary. Particulars of the Secretary at the Hospital.

King's College, London. The Chairs of Materia Medica and of Comparative Anatomy.

King's College Hospital. Physician, Honorary.

Owen's College, Manchester. Professorship of Anatomy. Emoluments from stipend and fees, guaranteed not to be less than £500 per annum. Full particulars on application to Dr. Greenwood.

Stockport Infirmary. House Surgeon. Salary, £60 per annum, with board and apartments. Address the Hon. Sec.

West Norfolk and Lynn Hospital. House Surgeon and Secretary. Salary, £80 per annum, with board, lodging, and washing. Testimonials, &c., to be sent to the Weekly Board, King's Lynn.

Rochdale Infirmary. House Surgeon. Salary, £100, with board and residence. Applications to Mr. E. M. Roys, Clover Cottage, Rochdale.

Kingston Union. Medical Officer for the new Radnor District. Salary, £80, with extra fees. Application to the Clerk before the 25th.

North Staffs. Infirmary. House Physician. Salary, £80 per annum, with board, &c. Address the Secretary, Hartshill, Stoke-on-Trent.

Burnley Union. Medical Officer of Health. Inclusive salary, £500 per annum. Address the Clerk to the Sanitary Authority, Burnley.

University of Durham. Professorship in Biology. Salary, £450, with a portion of fees. Candidates must apply to the Secretary of the College of Physical Sciences, Newcastle-on-Tyne.

Ceres, Fifeshire. Resident Medical Officer to the Board. Salary, £23, with fees extra. The appointment will also entitle the holder to be Medical Officer to the Adamson Institution with a salary of £43 per annum. Applicants must address—The Inspector.

Hartlepool Hospital. House Surgeon. Salary commencing at £80 per annum, with board and residence. Address the Secretary.

Northampton Infirmary. House Surgeon. Salary, £125 per annum, with board and lodging. Applications to the Secretary.

Northampton Infirmary. Assistant House Surgeon. Salary, £80, with board and lodging. Address the Secretary.

Bristol General Hospital. Physician, Honorary.

#### APPOINTMENTS.

BADDOCK, L. C., M.D., M.R.C.S.E., Public Vaccinator for the Central District of the Parish of Brighton.

BROWN, Mr. G. B., a Demonstrator of Anatomy at University College.

CROLY, R., L.K.Q.C.P.I., L.R.C.S.I., Medical Attendant to the Royal Irish Constabulary, Crossakiel and Kno ckrath.

GLANVILLE, J., M.R.C.S.E., House Surgeon to the Seamen's Hospital, Greenwich.

GRAYSON, F. D., M.R.C.S.E., Medical Officer for the Hadleigh District of the Rochford Union.

KINGSLEY, G. T. B., L.R.C.P.Ed., L.F.P. & S. Glas., Medical Attendant to the Royal Irish Constabulary, Borrisokane, co. Tipperary.

KNIGHT, C. F., M.R.C.S.E., Medical Officer to the Farringdon Road Workhouse of the Holborn Union.

MOORE, J., M.R.C.S.E., Medical Officer for the Eastern District of the Parish of Brighton.

OATES, J. P., M.R.C.S.E., Medical Officer for the Tanworth No 1 District of the Solihull Union, Warwickshire.

OWEN, R. E., M.R.C.S.E., Medical Officer of Health for the Beaumaris Urban Sanitary District.

PHILPOT, C. W., M.D., Certifying Factory Surgeon at Croydon.

PILKINGTON, H. O., M.R.C.S.E., Medical Officer of Health for the Preston Urban Sanitary District.

RAKE, B., M.R.C.S.E., Medical Officer and Medical Officer of Health to the No. 2 District of the Fording Bridge Union.

ROSS, J. H., M.D., M.R.C.S.E., Public Vaccinator for the Eastern District of the Parish of Brighton.

SHAPLEY, Mr. H. T., Junior Resident Medical Officer to the London Hospital.

THOMPSON, J., M.D., Medical Officer for No. 5 District of the Barnstable Union.

TURNER, W. M., M.R.C.S.E., Assistant Medical Officer to the Staffordshire Lunatic Asylum, Stafford.

WALLACE, A., M.D., Certifying Factory Surgeon at Turfiff, Aberdeen-shire.

WELBY, W. M. H., M.R.C.S.E., Assistant Visiting Surgeon for Shorncliffe, under the Contagious Diseases Acts (Women).

#### Birth.

GRAIFFITHS.—On the 1st inst., at 2 Sydenham Road, Dundrum, Dublin, the wife of Dr. Handel Griffiths, of a son.

#### Marriages.

DURANT—TOWNSHEND.—On the 2nd inst., at St. Marylebone Church, London, Edmund Durant, M.R.C.S.Eng., to Mary Ann Ada Absolom, eldest daughter of the late Lionel Townshend, M.D., of Attleborough, Norfolk.

#### Deaths.

BAKER.—On the 28th June, Thomas John Baker, Esq., M.R.C.S., of Junction Road, Highgate Hill, aged 68.

BROXHOLM.—On the 22nd June, J. Horton Broxholm, M.D., of Sunbury, aged 48.

DOUGLAS.—On the 25th June, Arch. Douglas, M.D., of Clifton Place, Hyde Park, formerly of Edinburgh, aged 57.

FLETCHER.—On the 27th June, Wm. B. Fletcher, Surgeon, of Rainford, Lancashire.

M'NICOL.—On the 22nd June, John Clark M'Nicol, M.D., of Clayton-le-Moors, Lancashire, aged 29.

O'CONNOR.—On the 19th June, T. J. H. O'Connor, L.R.C.P.Ed., of Heyworth Street, Everton, Liverpool, aged 34.

PEDGRIFT.—On the 22nd June, Robert Pedgrift, L.S.A.L., of Laddon, Norfolk, aged 78.

SCOT.—On the 25th June, at Laurencekirk, Thos. Goldie Scot, M.D., Deputy Inspector-General of Hospitals.

SMIRTHWAITE.—On the 19th June, Geo. Smirthwaite, M.R.C.S.E., of Coal-Clough, Burnley, aged 55.

**WANTED.**—A GENTLEMAN is desirous of DISPEN-SARY DUTY in any part of IRELAND for a few months. He is a Licentiate of the King and Queen's College of Physicians, and of the Royal College of Surgeons in Ireland.—Address C. W., office of this Journal, 23 Ely Place, Dublin.

**OWEN'S COLLEGE, MANCHESTER.**—PROFESSORSHIP of ANATOMY.—The Council propose to make an appointment previous to the commencement of the next Winter Session of a PROFESSOR of ANATOMY in connection with the Medical Department of the College (with which is now incorporated the Manchester Royal School of Medicine, founded in 1824), and they invite gentlemen willing to become candidates to send in applications and testimonials addressed to the Council, under cover to the Registrar not later than Saturday, the 1st August next. The emoluments of the office will be derived from a stipend and a share of students' fees, and the Council will guarantee for a certain term that these together shall not be less than £500 per annum.

Further information will be given on application to J. G. Greenwood, LL.D., Principal of the College.  
23rd June, 1874. J. HOLME NICHOLSON, Registrar.

**DUBLIN INFIRMARY for DISEASES of the EYE and EAR, Ely Place.**

Ophthalmic and Aural Surgeon:  
**ARCHIBALD HAMILTON JACOB, M.D. Dub., F.R.C.S.,** Ex-Ophthalmic and Aural Surgeon to the City of Dublin Hospital.

Consulting Physician:  
**EVORY KENNEDY, M.D. (Hon. Caus.), T.C.D. and Edin.,** Fellow and Ex-President King and Queen's College of Physicians.

Consulting Surgeon:  
**GEORGE H. PORTER, F.R.C.S.I., M.Ch. T.C.D. (Hon. Caus.),** Surgeon in Ordinary to Her Majesty the Queen in Ireland; Fellow and Ex-President, R.C.S.I.; Senior Surgeon to the Meath Hospital.

Obstetric Physician:  
**JOHN CRONYN, M.D., F.R.C.S.,** Examiner in Midwifery, Roy. Col. Surgeons; Ex-Assistant Physician Rotunda Hospital.

Work, Income, and Expenditure for Twelve Months, ending

June 30, 1873.

Annual number of Dispensary patients	...	...	729
Number of visits paid by such patients	...	...	5,847
Number of patients within the Infirmary	...	...	124
Number of operations performed	...	...	163
Total gross expenditure per bed per annum	...	£37	15 0
Average expenditure per intern patient	...	1	10 6

The Infirmary is wholly dependent on private benefactions, and is in debt to the Medical Officer. SUBSCRIPTIONS ARE EARNESTLY REQUESTED

**THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.**

PATRON:—H.R.H. THE PRINCE OF WALES.

This Institution was founded in 1839, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote. Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office.

40 MOLESWORTH STREET, DUBLIN,  
W. O'NEILL, Secretary.

**BUTLER'S MEDICAL HALL,**  
53 & 54 LOWER SACKVILLE STREET,  
DUBLIN.

ESTABLISHED A.D. 1817,

For Compounding Prescriptions and Supplying Genuine Medicines, is conducted, as formerly, under the careful superintendence of

WILLIAM STARKEY, M.D.,  
Licentiate Apothecary.

**The Medical Press and Circular**  
OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

Established 1848.

**PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.**

50 LINCOLN'S INN FIELDS, W.C.

**J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,**  
&c. (KING'S COLL.), and Author of *VIA MEDICA*.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

**PRACTICES AND PARTNERSHIPS NOW OPEN** for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

**Y 980. LONDON.** Secure investment. For sale, an OPEN SURGERY and RETAIL, the receipts from which are about £600 a year, nearly the whole being taken in cash. The Incumbent has left it chiefly to the management of an assistant, and it is estimated that if it were conducted by an active resident proprietor the receipts might be doubled. The house contains eight rooms, and is situate in a principal thoroughfare, near a railway station. It can be taken furnished if desired. There is no opposition in the neighbourhood.

**Y 979. DEATH VACANCY in a LONDON SUBURB.** The average receipts have been about £550, but the Practice has not been pushed. A good introduction can be given by the widow. The fees charged are good, and the patients chiefly upper middle-class. The house is convenient, well situate, contains ten rooms, and is held on beneficial lease at a rental of £50 a year. An efficient *locum tenens* is in charge. To a gentleman desiring an introduction to suburban practice this succession presents an unusual opportunity.

**Y 978. EXCELLENT NUCLEUS,** suitable for a gentleman with surgical experience. Receipts last half-year, £192; previous half-year, £158. There are special prospects of extension, and the Incumbent is only induced to leave by the offer of a good foreign appointment.

**Y 977. OPENING FOR PRACTICE.** A doubly-qualified gentleman with 100 guineas at his command can be introduced as the SUCCESSOR to a Death Vacancy in a Pleasant Town near the borders of Wales. Population of the town and district, 5,000. Probable income, £700 a year. Only one medical firm in practice.

**Y 976. DEVONSHIRE,** in a pleasant town. An efficient personal introduction can be given to a PRACTICE formerly yielding £700 a year. The Incumbent having sufficient means, has been gradually retiring, but the best residents in the locality will accept his nominee. A very convenient house can be purchased or hired at a low rent. As it is probable that a new mining enterprise will shortly attract a very large additional population, there is unquestionable scope for increase. The greater part of the premium can be paid by instalments.

**Y 928. PARTNERSHIP and SUCCESSION.** A most unusual opportunity is afforded to a gentleman doubly-qualified, and about thirty years of age, to enter a Practice yielding upwards of £1,100 a year, with a partnership introduction of two years and a half. The connection is in London, consists chiefly of good middle-class patients residing within a narrow area. Midwifery fees from £1 ls. to £5 5s. Appointments, £350 a year. No horse or carriage necessary, and all expenses moderate. Easy terms would be conceded to a suitable gentleman ready to enter upon the duties at once, but no one need apply who has not at least £750 at command.

DR. LANGLEY'S QUARTERLY LIST of Selected Partnerships and Practices for July is now ready. Sent post free on application.

### NOTE ON THE HYGIENE OF PARIS BESIEGED.

By Surgeon-General C. A. GORDON, M.D., C.B.

LET us hope that never shall we need the lessons in regard to the Hygiene of Paris Besieged to be applied under similar circumstances to a city in which British troops are placed. Nevertheless, as hopes and facts are unhappily on occasions at variance, I may briefly allude to some of the measures taken during the investment of the French capital in 1870-71. The measures resolve themselves into those connected with personal hygiene and those of public hygiene. The first had reference more especially to the troops of different kinds engaged in the defence. It was pointed out to them that of 100 deaths they must expect 75 to be by disease, and that therefore their first object was to guard against illness. First among the instructions published was the inculcation of sobriety, its importance being unhappily early shown by the rapid increase of excesses. It was pointed out that indulgence in "drink" renders a person more liable than he would otherwise be to the effects of cold and exposure, besides leading him to commit indiscretions before the enemy which might lead to his being killed or wounded. Instructions were given in regard to the best means of preparing food at the outposts and on the ramparts. A system was inaugurated to ensure personal cleanliness; nor was it by any means unnecessary: special provisions were made to supply the men with clothing and articles of bedding, but the circumstances of the siege did not admit of either being complete. Huts were erected in the more spacious thoroughfares and near the ramparts for their accommodation; some men were billeted in hotels and private houses, and public buildings were converted into temporary barracks. Canteens were established at convenient points, and steps taken as far as possible to supply the troops with hot meals before going upon and after coming off guard. The encouragement given in the French army to singing and dancing, although in accord with the genius and tastes of the people, would seem strange to us. Both were at a discount throughout the siege, except, indeed, that in the absence of instrumental music some of the newly-raised regiments marched out to battle singing as they marched the "Marseillaise" and "Mourir pour la Patrie."

With regard to public hygiene, the Central Committee of Salubrity at once co-operated with the Intendence, with a view to make such arrangements as could be carried out without the aid of medical officers, for, strange as the circumstance must appear, they were in many instances not consulted at all, and when they were, their views not necessarily accepted. The four great effects of a siege were early anticipated, and prepared for as far as circumstances permitted. These were battle, fire, famine, and disease. To the success of arrangements thus early made must be assigned the fact of absolute famine having been postponed for more than a hundred days, and disease having been limited to a rate of only five times greater than what it is under normal conditions. Measures were taken to provide accommodation, food, and other requirements for the many families from the outskirts of the city who crowded into it, and for the reception of the sick and wounded, who, it was felt, would come in great numbers. In respect to the latter, it must be said that tents and huts were erected, public and private buildings utilised for the time being, but unfortunately, sanitary requirements not in all cases fully attended to, so that, more especially in the wounded, mortality ran high from hospital diseases. After a time the very dead became a source of danger to the living, those who had perished by wounds and their effects exhaled alike in their latter hours and in their death emanations that even the use of disinfectants could scarcely overcome. Thus a special arrangement for their speedy interment became a matter of great public importance. As far as possible it was arranged that regiments should take their tours of duty on the advanced posts, and on the ramparts every third day, but this was liable to frequent disturbance by reason of collisions and more important actions with the enemy. It will be remembered that one of the earliest measures taken was to get rid of the *bouches inutiles* as far as that could be effected. In doing so a number of foci of disease were also disposed of, with the somewhat strange result that after the dearth of fuel and oil had caused the public thoroughfares to be in darkness after an early hour in the evening, those whose duty it was to traverse the city were able to do so almost without molestation. The resources of the public service being altogether inadequate to meet the requirements; the co-operation of the medical profession and public at large was solicited for services connected with hospitals and ambulances, and to the credit of all, it must be said that they most freely, fully, and effectually responded to the call. Organisations of various kinds by societies under the Red

Cross of Geneva were formed; help in money, material, and in personal service were freely given, and by none more freely than by the ladies, whether of sisterhoods or "of the world." At a later period much of the transport of the wounded from the field of battle, as also their subsequent accommodation and treatment, was carried out by such organisations. Employment was given to every one who desired or could be induced to take it, whether belonging or not to the regular army or national guard. The troops needed clothing and shoes, the streets, rivers, canals, and houses had to be maintained in a state of cleanliness, nuisances had to be burnt for want of means of removal, defences thrown up, preparations made to decrease, as far as possible, the risks of fires in public and in private buildings, thus affording to all means of labour and remuneration. Under the Supreme Council of Salubrity, sub-committees, each with its organisation, were appointed to superintend respectively food, water, conservancy, and house accommodation. By this systematic division of labour much was effected to avert disease which otherwise would have been inevitable, and to serve as an example in the case of any other city unhappily placed under similar circumstances. Specific rules were laid down in regard to cleansing and disinfecting wards or apartments in which persons wounded or suffering from disease had been accommodated; and with reference thereto I may observe that, as a rule, the results of artificial disinfection were by no means encouraging, inasmuch as hospital disease having once occurred in a building, disinfection and cleansing, however carefully performed, failed to eradicate it. The only sure plan of effecting this was to abandon the building. It soon was discovered that irregularities of various kinds were taking place at the *abattoirs*, and that substances were being sold for food which were in reality unwholesome. The committee charged with the supervision of such matters directed their attention to them; the former were brought under very strict supervision: the animals, whether chevaline or bovine, intended for slaughter were carefully inspected; such as were at a later period established as "*boucheries des chiens, des chats, et des rats*," were similarly supervised, and all dépôts of food strictly inspected. At all times throughout the siege a ration of wine was issued for every *moult* in Paris; canteens were established at which the very poor received daily their allowance of food at the expense of the municipality, thus for the time being placing them upon a better footing than the better classes; and the result of the arrangement was that when our famine was at its height, famine fever was non-existent among us. This fact has since the siege been commented upon, as indeed it deserves to be, by various writers, the conclusion very naturally arrived at being that the freedom from such disease enjoyed by the besieged arose in an important degree, if not altogether, from the fact of wine being regularly issued to them. Another measure which cannot be passed over was the cultivation of every available space of ground for salads and vegetables, so that throughout the whole winter it was possible to obtain such antiscorbutics, although in small quantity, and not to altogether prevent a general taint from pervading the masses of the besieged.

In the early part of the investment, and before the besieging circle had yet closed tightly in around us, every thing in the shape of food that could be obtained from outside was collected in the interior, cattle, sheep, and horses were brought within the barriers; the two former were placed in pens along the Boulevards, and daily provided with rations of fodder, the rate at which the animals were subsequently killed being arranged with reference to the means of supplying them with appropriate food; the horses were as long as possible used for purposes of draught. From time to time the quantities issued as rations were decreased, until, when capitulation took place, the sole food daily allowed to an adult was 10½ ounces of coarse bread and a quarter of a litre of wine. Nor were the wounded much better provided for; deaths among them were fearfully numerous, and Paris itself was starved into capitulation.

## STUDENTS' COLUMN.

### LECTURES ON HUMAN ANATOMY.

By WALTER RIVINGTON, M.S. Lond., F.R.C.S. Eng.,  
Surgeon to the London Hospital and Lecturer on Anatomy at the  
London Hospital Medical College.

#### LECTURE X.

(Continued from page 12.)

THE breadth of the Sternum is not entirely a human character. Man shares this feature with the gorilla, chimpanzee, orang, and gibbon, in fact, with all the Anthropoid Apes. The lower monkeys have narrower Sterna, composed of pieces which continue separate throughout life. The unusually broad Sternum occasionally seen in man may be compared to the broad Sternum of the Siamang gibbon; the unusually narrow Sternum, with the Sternum of many of the lower Mammalia, including the dog and the kangaroo, now present in skeleton on the table. That earlier condition of the Sternum in man, in which it is composed of several segments united only by cartilage, is represented by the permanently segmented state of the Sternum in many orders of the Mammalia, the pieces being united either by fibrous tissue or separate synovial joints. The imperfect union of the Sternum in the middle line brings up the Sternum of the pig, which "very often retains indications of the primordial median fissure throughout life," (a) and the transitory cleft of the bone in the Struthious Birds.

The presence of the Manubrium without the rest of the bone, observed in man by Chaussier, (b) is a condition paralleled by the whale-bone whales, in whom the rest of the Sternum aborts, or is present only as a Xiphoid Process. In Birds the representative of the lower part of the Sternum or Xiphisternum is greatly developed. In the ostrich and cassowary it is simply expanded into a broad plate. In other birds it gives off in front a keel-like process, which affords attachment to the muscles which move the wings. A keel-like ridge is found in some Mammals, and has been mentioned as sometimes present in man. It is very rare.

The *Ribs* are long narrow curved bows of bone composed of two layers of compact tissue enclosing cancelli. In this respect they bear an analogy to what are called the *Flat Bones*. The *Ribs* are divided into 3 sets, according to their terminal connections. The upper 7 articulating behind with the Vertebrae, and ending in front in Cartilages which join the Sternum independently of each other, are called the *Vertebro-Sternal* or *True Ribs*. The three succeeding Ribs articulating behind with the Vertebrae, and ending in front in Cartilages which are joined to the Cartilages immediately above them, the 8th to the 7th, the 9th to the 8th, and the 10th to the 9th, are called *Vertebro-Costal*. The two last Ribs articulating behind with the Vertebrae, and ending in front in Cartilages which are "free and independent" are termed *Vertebral*, or *Floating Ribs*. The *Vertebro-Costal* and *Vertebral Ribs* are called collectively the *False Ribs*. All the Ribs have common characters more or less distinctly marked. They form segments, or arcs of circles, and have 2 *Surfaces*, 2 *Borders*, and 2 *Extremities*. The typical characters of these parts can be studied best on one of the central Ribs. Taking for instance the 5th or 6th Rib, and looking at the articulated skeleton, you will notice that it is jointed behind to two vertebrae and their intervening disk. From this point it slopes downwards and backwards to the transverse process of the lower Vertebra, and is united by a distinct articulation to its extremity; it continues a little further in the same direction, and then making a rather sudden bend, passes downwards and forwards in a gentler curve to its termination and junction with the Costal Cartilage, which runs upwards and inwards to articulate with the margin of the Sternum. Each part has a separate name. The expanded vertebral extremity is called the *Head*, the flattened part succeeding the Head and resting against the transverse process of the Vertebra is called the *Neck*, the enlargement at the outer end of the Neck, which joins the end of the transverse process, is the *Tubercle*; the remainder of the Rib is the *Body*, or *Shaft*, and the point where the Rib alters its direction, is marked on the outer surface by a line called the *Angle*.

The *Head* presents at its extremity two articular surfaces, or facets, separated by a ridge, which corresponds to the inter-

(a) Flower, op. cit., p. 77.

(b) Smith's Osteo., p. 210.

vertebral fibro-cartilage, and gives attachment to a ligament called the inter-articular ligament, separating the joint formed by the upper facet with the vertebra above from the joint formed by the lower facet with the vertebra below. The *inferior facet* is larger than the other, and has but a slight obliquity. The *superior facet* is cut with considerable obliquity, corresponding in this respect to the facet on the upper vertebra. Both facets are slightly concave, covered with cartilage, and form an angle with each other. The mode in which the *Head* is wedged in between two Vertebrae contributes greatly to the security and stability both of the Ribs and Vertebral Column. The more horizontal direction of the upper facet is designed to act as a stop and efficient bearing point for the Head of the Rib when pressed upwards in the respiratory act.

The *Neck* is not always constricted, as the name might lead you to suppose, but flat, and wider than the neighbouring part of the shaft. It is about an inch in length. Its *anterior surface* is smooth and concave; its *posterior surface* is rough, attaches a ligament at the lower part, and presents the orifices of canals running in divergent directions, which give passage to small vessels for the nourishment of the bone. The *superior border* is elevated into a crest, which attaches a ligament; the *inferior border* has two distinct margins, anterior and posterior. The *Neck* is designed as a means of junction between the Rib and the transverse process, and its peculiarities have reference to their correspondency and ligamentous connections. In front it supports the thick posterior border of the lungs.

The *Tubercle*, or *Tuberosity*, which is placed at the junction of the *Neck* and *Shaft*, consists of two parts, an inferior and internal, smooth, convex, and covered by cartilage for articulation with the concave facet on the extremity of the transverse process, and a superior and external rough portion, which attaches a ligament. The former is generally called the *articular* and the latter the *non-articular* portion (a). The *Tubercle* is an additional provision for securing the Rib to the transverse process whilst permitting the requisite movements between them.

The *Body* of the bone is convex on its *outer surface*, smooth, and marked by the prominent *angle* which runs obliquely downwards and outwards. Near the sternal end there is a feeble line, called the *Anterior Angle*. The *Internal Surface* is concave, and presents below its middle a *Ridge*, which begins at the *Head*, runs along the *Neck* and *Shaft*, gradually diminishing in prominence till it disappears near the anterior end. Between the ridge and the inferior border is a deep *Groove*, which commences opposite the *Tuberosity*, runs towards the anterior extremity, becomes more marked at the angle, and then gradually diminishes and disappears in the anterior third. In this groove are seen the orifices of canals for the blood-vessels which nourish the bone. They run with much regularity backwards towards the *Head*. It is stated by most anatomists (Ward, Quain, Gray, Holden, Ledwich, Harrison, South, &c.) that the *Groove* lodges the *Intercostal Vessels* and *Nerves*. Humphry speaks of the *Groove* as the "so-called *Groove* for the *Intercostal Artery*." Wilson flatly denies that the vessels ever run in the groove. This is certainly an error. The fact is that the intercostal arteries vary in the different spaces and in different subjects, extending outwards for an uncertain distance before seeking the shelter of the groove. Protection to the vessels appears to have been a *secondary* and not a *primary* object of the groove. The *Superior Border* of the Rib is thick and rounded. The *Inferior Border*, the segment of a larger circle than the superior, is thin and sharp. The *Anterior Extremity* presents a deeply concave cup for the reception of the tough cartilages, or "gristles," by which the Rib is continued to the Sternum.

The concavity and smoothness of the internal surface of the Rib have evident reference to its forming the boundary of the Thoracic Cavity, and its contact with the Pleura, or investing membrane of the lung. The thickness of its upper border is needed for the attachment of the 2 intercostal muscles, internal and external. The thinness of the inferior border is explained by the presence of the ridge on the inner surface, for the latter attaches the internal intercostal muscle, and the former the external. The groove represents the interval between the intercostal muscles, and protects the intercostal arteries. The angles strengthen the Ribs at a weak point, and are for the attachment of the tendinous fibres of muscles. To the posterior angle the tendons of the strong erector

muscle of the back are affixed. The interval between the angle and tuberosity is occupied by muscular fibres.

Placing the Rib on its lower edge on the table, you will find that the Posterior Extremity from the Angle to the Head is tilted upwards and forwards, forming with the anterior portion an obtuse angle, whose apex points downwards. It would appear as if, while the Rib was still in a soft cartilaginous condition, its anterior part had been turned forwards near the angle, and then curled over a little from without inwards. This is what is meant when the "twists" of the Ribs are mentioned in anatomical text-books.

Tracing next the outlines of these two portions on a slate, or on paper, or merely taking a "bird's eye view" of the Rib, you will perceive that at or near the angle is the point of junction of the segments of two circles of different sizes. The posterior part, which is more sharply curved, is the segment of a circle comparatively small; the anterior part, which has a more gradual curve, is the segment of a circle considerably larger.

Looking at the skeleton, you will see that the anterior extremity of the Rib is lower than the posterior; that the Rib slopes obliquely downwards from the vertebral attachment. All these three peculiarities have reference to the movements required for enlarging and diminishing in respiration the capacity of the chest.

Place one of the Central Ribs with its lower edge on the table, and its anterior end towards you. Raise the anterior end, keeping the opposite end in contact with the table, and you will observe that the Neck of the Bone is rotated on its axis, and that its anterior surface, which naturally looks slightly upwards, is turned still further in that direction. The inference is that when the anterior ends of the Ribs are raised, the posterior ends are rotated. Now keep the two ends on the table, and raise the middle portion of the Rib, rotating it on an axis drawn through the vertebral and sternal ends. In this motion the Head is nearly fixed, but the Neck is raised, especially at its outer end, where its articular facet is situated. These two movements are almost exactly the movements which take place in inspiration. The anterior ends of the Rib, which we have already seen are considerably lower than the posterior, are raised so as to bring them more nearly to a level with the posterior, and the central parts of the Rib, which lie below the level of a line drawn through their two extremities, are also raised, and these two changes must necessitate a rotation of the Neck of the Rib and an elevation of its outer end. This view is corroborated by the position of the ligaments, which is exactly such as to limit these movements, as well as by the disposition of the muscles, which is exactly such as to produce them. It is a universal law, that where there are joints which are capable of particular motions, there are muscles capable of producing the movements, and ligaments or some other provision for preventing these movements proceeding too far. There is always an exact relation between the joint, the muscles which move it, and the ligaments checking the movements.

Arranging the Ribs in order on the table you will observe some of their

#### DIFFERENTIAL CHARACTERS.

The Ribs are not mere repetitions of each other. Humphry well observes: "The twelve Ribs present a good illustration of that resemblance in general features and dissimilarity in details which pervade more or less the various parts of the skeleton, and which may indeed be observed throughout the whole physical world to constitute a general law of creation. They are alike in the plan of their construction, yet each one differs from the other in certain particulars." A good observer would readily distinguish any Rib that might be presented to him.

The *Length* of the Ribs increases from the 1st to the 6th or 7th, and diminishes from the 7th to the last. The 12th Rib is the shortest, the 1st Rib comes next in order of brevity, and then the 11th, which is shorter than the 2nd.

In *Breadth* the Ribs narrow in regular sequence to the last, the 1st Rib exceeding all the others. In degree of *curvature* the 1st Rib has the pre-eminence. The curves of the rest diminish to the 12th, which is scarcely curved at all. As the 12 Ribs lie upon the table the 1st is seen to rest evenly between its extreme points; the head of the 2nd is a little raised, and this *upward inclination of the head* increases as far as the 8th, and then diminishes to the 12th. Looking at the position of the Ribs in the skeleton, we notice that their downward obliquity increases from the 1st to the 9th, and then diminishes to the 12th. Moreover, the *aspects* of their sur-

(a) It might be as well to call the smooth articular part the *Tubercle* and the rough ligamentous part the *Tuberosity*.

faces vary. The surfaces of the 1st Rib look upwards and downwards, and its borders inwards and outwards. The surfaces of the 2nd have an inclination outwards and inwards as well as upwards and downwards. The inclination becomes greater in the 3rd and 4th. The 5th, 6th, 7th, 8th, 9th, 10th, and 11th look inwards and outwards. In the 12th the outer surface is turned a little *downwards*, and the inner surface *upwards*. These peculiarities in *length*, *breadth*, *curvature*, and *aspect* specially relate to the shape of the Thorax. All the peculiarities have reference to the amount and kind of motion of which each Rib is capable. The *Heads* of the 1st, 10th, 11th, and 12th, have each a single oval facet for articulation with one dorsal vertebra only; the rest have two facets. The *Necks* of the 1st, 2nd, and 3rd Ribs are slender, but strong. The neck of the 1st is flattened from above downwards, that of the 2nd is prismatic, and that of the 3rd is flattened from before backwards, like the necks of the rest of the Ribs. The neck of the 4th is wider, the *crest* on the upper border beginning to appear, and gradually becoming more prominent to the 9th. In proportion to the elevation of the crest and the descent of the lower border is the width of the neck. In length the neck diminishes in the 10th, 11th, and 12th. In the 11th the neck is regarded as absent.

The *Tuberosity* of the 1st is prominent on the outer border of the Rib, and bears a facet convex from above downwards and elongated transversely. The facet on the 2nd has a similar shape. The other facets are round or oval, situated on the posterior surface of the neck near its lower border, and sometimes projecting underneath the latter, so as to be visible from the front. The *Tuberosity* is usually absent from the 11th and 12th Ribs, but I have seen the 11th and even the 12th articulating by means of a small facet with the transverse process of its corresponding Dorsal Vertebra. In this lecture-skeleton the 11th Ribs articulate with the Transverse Processes by means of considerable facets. I have noticed this in several subjects, and believe that it occurs more frequently than is generally supposed.

The differences in the slope of the Ribs from their vertebral to their sternal ends relate to the degree to which their anterior ends are capable of being raised in inspiration. The greater the slant the greater will be the capacity for elevation, and it will be evident that this capacity will be most considerable in the 8th and 9th Ribs. The differences in the mode in which the posterior segments join the anterior segments of the Ribs, as shown by the relative inclination upwards of their heads when the Ribs are placed on a flat surface, would appear to bear reference to the degree of elevation of which the middle portions of the Ribs are capable as well as to the elevation of their anterior ends. The differences in the articular facets on the Heads, in the Necks, and in the shape of the articular facets on the Tuberosities correspond with the kind of motion performed by each Rib. The 1st Rib, lying evenly between its extreme points, having a single facet on the Head, a Neck flattened from above downwards, a convex facet on the Tuberosity elongated transversely and passing horizontally outwards to the ascending Transverse Process of the first Dorsal Vertebra, is adapted for moving on a transverse axis drawn through its Head and Neck. Its movement is one of simple rotation on this axis, by which means its anterior end, carrying the Manubrium, is merely elevated and depressed. In proportion as the Necks become flattened from before backwards as the facets on the Tuberosities become rounded or elongated from above downwards, and as the anterior and posterior segments of the Ribs unite at a sharper angle and more unevenly, in the same proportion do the Ribs acquire movements compounded of elevation of their anterior ends (which it will be remembered involves rotation of the Necks), and of elevation of the middle portion of the Ribs (which involves raising of the outer ends of the Necks and Tuberosities). In rotation of the Neck, the convex facet on the Tuberosity (or convex *Tubercle* as it may best be called) rolls in the concave facet on the Transverse Process, and tends to descend; in elevation of the Neck the Tubercle ascends, sliding on the facet on the Transverse Process. These compound movements will be most marked about the 8th or 9th.

The *Angle* in the 1st Rib corresponds to the Tuberosity, and in the 2nd is close to the Tuberosity. In the rest the interval between the Angle and the Tuberosity increases gradually to the last Rib, on which a little roughness only is distinguishable.

The development of the *Ridge* is deserving of attention. In the 1st Rib it corresponds to the inner border of the bone. In two or three of the following Ribs it is found running only

a short course, and ending perhaps in the upper border of the bone. In all the rest it begins at the lower border of the head, and pursues its way on the shaft till it is lost in the lower border. From the account given of the Ridge in our text-books, we should infer that it was an addition to the Rib, the simple line of insertion of the internal intercostal muscle, at the best a buttress or a ridge, and nothing more. Examining a Rib more carefully, we observe that the Neck in some has two margins to its under border, an anterior and a posterior. The anterior margin continued on to the shaft is the Ridge; the posterior margin runs to the Tubercle, by which it is interrupted, and then becomes prolonged forwards, as the lower border of the shaft. In other Ribs the posterior margin of the Neck is suppressed, and the lower border of the shaft of the Rib commences at the tubercle. Looking at the Ribs from the front, we see that the Ridge is the *continuation of the lower border of the Neck*. The groove and the lower border of the shaft appear to be additions to the Rib, and the Rib is made more symmetrical by their removal with the saw.

The *Groove* is absent from the 1st and 12th, short on the 2nd Rib, gradually lengthens to the 9th, and then as gradually the lower border of the shaft dies away.

The comparative development of the *Angle*, the *Ridge*, and consequently the *Groove*, bears a strict relation to the length and strength of the individual Ribs, and their importance as instruments for increasing the capacity of the chest in the respiratory act. Recollect that ridges on bones generally attach processes of fibrous tissue, and either ligaments or the tendons or tendinous fibres of muscles. The development of a ridge, or a rough surface for a muscle, is in exact proportion to the strength of the muscle, and the growth of both increases with equal steps. The more prominent therefore the angle or the ridge of the Rib, the more powerful will be the muscle attached to it. Recollect also that the power of a muscle in moving a joint has an exact relation to the distance of its attachment from the centre of motion, and the comparative distances of the angle from the tubercle will be readily explained.

There are still some SPECIAL FEATURES of the 1st Rib requiring notice. We have mentioned the *position*, the *aspects*, and the *curvature* of the 1st Rib, its *single facet* on the *Head*, its *Neck* flattened from above downwards, its prominent *Tuberosity* corresponding to its angle, and its facet elongated transversely. The additional features are a convex outer border, round and thick behind, thin in front; a concave *Inner Border*, sharp, and bearing in the centre a *Tubercle*, a large and thick anterior end, and the impressions on its upper surface. This surface forms a flat shelf, or ledge, marked by the impressions of two large blood-vessels which it supports, and two muscles to which it gives attachment. The blood-vessels are the large artery and vein, which in their passage through the upper opening of the Thorax to and from the upper limb rest on the 1st Rib, and lying underneath the Clavicle, are called the Subclavian Artery and Subclavian Vein. The two muscles are named the *Anterior* and *Middle Scalene* Muscles, which are concerned in elevating and steadying the Rib; and they descend from the Transverse Processes of the Cervical Vertebrae to the 1st Rib like the shrouds or rattlins of a mast. For the Vein and Artery there are shallow grooves running from the inner to the outer border of the Rib, and separated by a *Ridge* or impression, which commences at the Tubercle, and gives attachment to the Anterior Scalene Muscle. The Tubercle and the Muscle are taken as guides to the Subclavian Artery in surgical operations. The Subclavian Vein lies in front, resting on the Anterior Scalene Muscle; then follows the Subclavian Artery, resting behind on the Middle Scalene Muscle. The impression for this muscle is rough, and extends from the groove for the artery as far as the Tubercle. The upper surface of the 1st Rib is marked also by a line which runs from the Tubercle forwards to the anterior border, and cuts off a rough surface externally. It is inside this line or ridge that the Middle Scalene Muscle is attached. On the 2nd Rib there is a similar ridge and impression, and on the middle of the outer surface is a rough elevation for the Serratus Magnus Muscle. The Posterior Scalene Muscle is attached to the hinder impression.

The *Costal Cartilages* have each two *surfaces*, two *borders*, and two *extremities*. The *Outer Surface* is convex, the *inner* concave. The *Superior Border* is concave; the *Inferior Border* is convex. In *length* the Cartilages increase from the 1st to the 7th, and then diminish to the last. In *breadth* they diminish from the 1st to the last. Their *outer ends* are implanted in the terminal cups on the Ribs, and are wider than their inner

## GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

SESSION 1874.

ends. Their *direction* varies. The 1st has a slight descent, the 2nd is horizontal, the 3rd ascends slightly; the others, at first descending in the direction of the Ribs, curve upwards and ascend more and more to their inner attachments.

The Costal Cartilages act as buffers in the concussions to which the Thorax is subjected, and by their elasticity they materially aid the movements of respiration. "A blow on the Sternum is distributed over fourteen elastic arches." (a)

The floating Ribs may be found reinforced by the 10th failing in its attachment, and the Costal Cartilages have often been observed to show curious irregularities of form and disposition. To the preparation in our Museum marked Cza 139, and included in our anatomical collection, I must call your special attention. It is a Sternum from an adult, probably a female, with the Cartilages of the Ribs attached to it. Neither the Manubrium nor the Ensiform Cartilage is ankylosed to the Gladiolus, but both are connected with it by soft tissue, apparently Cartilage. The 6th Costal Cartilages are partially united with the 7th, about two inches from the Sternum, and then run up to their usual separate points of junction with that bone. The 8th Costal Cartilages are also amalgamated with the 7th below, but above lie in close apposition to the 7th, and join the Sternal Column between the Ensiform Cartilage and the Gladiolus. This specimen appears to be, and has been considered to be, an example of the attachment of eight Ribs separately to the Sternal Column. The age of the person from whose body it was derived was probably between 30 and 40. It is not improbable, therefore, that the 7th and 8th Cartilages might have united further later in life. Another specimen in my possession which I removed from the body of a female, has eight pair of Ribs articulated with the Sternum. Professor Humphry, of Cambridge, mentions in his work on the Human Skeleton, that a similar specimen exists in the Anatomical Museum of Cambridge, but he does not tell us whether it belonged to a male or a female. I have little doubt that if attention were directed to the point it would be found that such a peculiarity is not uncommon, and it might be interesting to note whether it occurs more commonly in the female or in the male.

In *structure*, the Costal Cartilages, according to Todd and Bowman, occupy an intermediate place between the Cartilages which are found in the joints, or the *Articular* Cartilages, and the Flat Cartilages, or *Membraniform* Cartilages composing the walls of the Larynx. The cells are very large, with two or more nuclei, and have a linear arrangement. The intercellular substance is abundant, and has a fibrous appearance. In old age bony matter becomes deposited in the Cartilages.

The *Ribs*, although in point of shape Long Bones, are in point of structure *Flat* Bones, being composed, as already stated, of two plates of compact tissue with intervening cancelli. They appear to have been originally regarded as strips of bone torn off from one large flat bone, for the term Rib probably means anything torn or ripped asunder, and the Ribs are the bones which extend separately and asunder from the back-bone. The split boards with which the sides of a ship are covered are called Ribs, and so are the divisions of the stalk forming the skeleton of a leaf. (b) In vulgar parlance a woman is called a Rib, because she was fashioned out of a Rib removed from Adam's side. (c)

(End of Lecture X.)

(a) Holden, "Osteology," p. 217.

(b) Encyclopedia Metropolitana, Article Rib.

(c) This use or misus- of the term would appear to be adopted in the American vernacular. In the "Biglow Papers," which abound in humour, Mr. Bird-o'-freedom Sawin, a Mexican soldier, recounting his bodily hurts and losses in the war, observes:—

"I've hed some ribs broke, six (I b'lieve), I hain't kep' no account on 'em; Wen pension gits to be the talk, I'll settle the amount on 'em. And now I'm speakin' about ribs it kin' o' brings to mind One that I couldn't never break—the one I lef' behind: Ef you should see her, jest clear out the spout o' your invention, An' pour the longest sweetest in about an annoval pension, An' kin' o' hint, in case you know, the critter should refuse to be Consoled, I ain't so 'xpensive now to keep as what I used to be: There's one arm le-s, ditto one eye, an' then the leg that's wooden Can be took off and sot away whenever there's a pud lin'."

In London the total number of deaths reported during the week was again below the average, being 1,336: zymotic diseases 203, including 86 of diarrhoea, 31 of scarlet fever, 28 of whooping-cough, 23 of measles, and from diseases of the respiratory organs, 322.

THAT "house and messuage," No. 315 Oxford Street, which had been once upon a time the College of Chemistry, has recently passed into the hands of the General Council of Medical Education, at an annual rental of £300, and after an expenditure by the Government of £1,500. On Thursday last, for the first time, its doors were publicly and officially thrown open for the reception and grave deliberations of its new tenants, and although it is in quite an unfinished state, paintless to a great degree, carpetless in part, and we fear we may add damp, just at present, still, from its capacity, its central position, and the accommodation it will afford for all purposes bearing on Council matters, the General Council of Medical Education and Registration have very good reason not only to be satisfied with their new premises, but also to be a little vain—were it possible for so subtle a "weakness" to penetrate into the midst of such an august assembly—of their leasehold.

For the information of those of our readers who may not have for some time to come an opportunity of visiting this Council-house, we may just observe that in external appearance it reminds us very much of the ordinary "detached villa" of our metropolitan suburbs—but it is not detached. The massive pillars bearing ornamental capitals give to the exterior of the building an appearance of solidity and ornamentation. Still, it looks square, squatty, homely, and comfortable. Its storeys from the footway are two. We enter from the street by a door which leads to a passage, or hall; this hall cuts the basement into two portions right and left of two rooms each, and subsequently conducts us to the stairs by which we descend to the Council Chamber. This chamber is situate at the rear of the rooms alluded to. These rooms are to be the several offices and waiting-rooms of the Council. The Council Chamber is square (about 60 by 60 ft.), lofty, lightsome, and at present wretchedly ventilated. With the exception of some really fine "marone" morocco-caparisoned chairs, escutcheoned in gold, what may prove to be—were it uncovered and relieved from the heavy burthen of medical literature that so *accumulatively* oppresses it—a capacious table, one or two smaller tables, and a carpet—to which we allude merely in order to note the fact, the Council Chamber is both unfinished and unfurnished, crude, paintless, and paperless. By a side-stair from the hall we pass to what had been intended for the reporters' gallery; it has not answered the purpose so far, consequently accommodation for the Press has been made to meet the present occasion by the introduction of side-tables and chairs in the vicinity of the members of the Council.

Above the four rooms alluded to are, we have been informed, large rooms intended to be used for select committee rooms, refreshment room, &c. The latter is well supplied just now, we have no doubt; yet we would be wanting in public duty and in respect to ourselves—cruelly we were about to add—and to those who may have to undertake duties such as ours at 315 Oxford Street, where the thermometer may range high as at present, were we to omit mention of the fact that milk biscuits at 6d. per lb. often cause dyspepsia, that the revivifying or tonic effects produced by the imbibition of claret we have some doubts about,—that *that* water, pure and simple, should be drunk—if it must be drunk—even during a few afternoon hours in midsummer, not *above* blood heat, and that we would much prefer—should we be ever again similarly placed—a few minutes' time during each sitting in order to visit the nearest confectioner, as thirst will come, and we disapprove the use of *hot* water, claret, and kindred stimulants, even on exceptional occasions.

The proceedings of the Council of Medical Education and Registration, so far as it has been yet possible to report them, including the President's address, we append, and from the proceedings that followed the reading by him of that document, it will be seen that he has determined, at the close of the session, to resign the chair he has filled with so much ability, strict impartiality, courteousness, and judgment during the years he occupied it.

The contemplated retirement of Dr. Paget is much to be regretted. Active, able, and consistent, the responsible duties undertaken by him have been performed, as we

have said, in such a becoming manner as to leave nothing to be desired, save a sincere wish that he might be induced to continue to guide with the same steady eye, and the same firm hand, the educational ship. The recent changes in the construction of the Council, the introduction of new, fresh, and vigorous blood into the crew of the ship as it were, and the hearty co-operation of Drs. Macnamara, Haldane, Begbie, and Professor Turner point to a bright future of usefulness for the General Council of Medical Education. Already the new councillors have displayed signs, not only of vitality, but of considerable animation and active life. In Dr. Haldane and Professor Turner our friends beyond the Tweed may feel—and we base our unassuming judgment on premonitory symptoms—perfectly satisfied that their interests are in safe hands; whilst in Dr. Macnamara the Irish College of Surgeons have secured a councillor, active—as he is universally acknowledged to be—able, cautious, thoughtful, and progressive, a gentleman whom the rank and file of the College he represents may regard as their faithful representative, proud of her history and the glorious reputation indelibly impressed on every page of it, anxious and chary for her future prospects and achievements.

#### MINUTES OF MEETING, THURSDAY, JULY 9, 1874.

315 Oxford Street, London, W.

Present—Dr. Paget, President, in the chair, Dr. Bennett, Mr. Quain, Mr. Bradford, Dr. Acland, Dr. Humphry, Dr. Pyle, Dr. Storrar, Dr. Andrew Wood, Dr. Fleming, Dr. Thomson, Dr. A. Smith, Dr. Leet, Dr. Apjohn, Sir D. Corrigan, Bart., Dr. Sharpey, Dr. Parkes, Dr. Quain, Sir Wm. Gull, Bart., Dr. Stokes, and Dr. Francis Hawkins, Registrar.

The minutes of the last meeting were read and confirmed.

Letters were read from Sir Dominic Corrigan and from Dr. Leet, stating that each of them had been prevented from attending at the hour appointed by the Council to-day through the necessity of attending to give evidence before a Committee of the House of Commons.

The following official notifications of the appointment of new members of the General Medical Council were then read.

Extract from Minutes of Quarterly Meeting of the Royal College of Physicians of Edinburgh, held within their Hall, the 4th day of November, 1873.

“The Royal College of Physicians of Edinburgh then, on the motion of Dr. Wood, seconded by Dr. Malcolm, in pursuance of the power given to them by the Medical Act, appointed Dr. Daniel Rutherford Haldane, of Edinburgh, a Fellow of this College, to be a Member of the General Council of Medical Education and Registration of the United Kingdom for the term of five years from this 4th day of November, 1873.”

A correct extract from the minutes of the Royal College of Physicians of Edinburgh, of 4th November, 1873.

(Signed) D. R. HALDANE, Secretary.  
CHRIS. DOUGLAS, Clerk.

The University, Aberdeen, 1st Nov., 1873.

We, the Principal and Masters of the University of Aberdeen, in pursuance of the power given to us by the Medical Act, do hereby appoint Professor William Turner, University of Edinburgh, to be a Member of the General Council of Medical Education and Registration of the United Kingdom for the term of five years from the 1st day of November, 1873.

(Signed) P. C. CAMPBELL, Principal.  
WM. MILIGAN, Secretary.

November 11th, 1873.

We, the Senatus Academicus of the University of Edinburgh, in pursuance of the power given to us by the Medical Act, do hereby appoint William Turner, M.B., Professor of Anatomy in the University, to be a Member of the General Council of Medical Education and Registration of the United Kingdom for the term of five years from the 19th day of October, 1873.

(Signed) JOHN WILSON, Sec. Senat. Acad.

Royal College of Surgeons in Ireland,  
Dublin, February 20th, 1874.

Sir,—I have the honour to inform you that Rawdon Mac-

namara, Esq., M.D., was elected yesterday Representative of this College on the General Medical Council for the space of one year from February the 16th, 1874.

I remain, Sir, your obedient servant.

(Signed) J. STANNUS HUGHES, Secretary.

Dr. Hawkins.

Council Office, Whitehall, Nov. 25th, 1873.

Sir,—I am directed by the Lord President of the Council to transmit to you for the information and guidance of all whom it may concern, the enclosed order of Her Majesty in Council of the 20th inst., appointing for five years from 20th November, 1873, Dr. Edmund A. Parkes, and Dr. Richard Quain Members of the General Council of Medical Education and Registration of the United Kingdom for England, and appointing Dr. J. Warburton Begbie for Scotland, and reappointing Dr. William Stokes for Ireland.

I am, Sir, your most obedient servant,

(Signed) E. HARRISON.

The Registrar, General Council of Medical  
Education, 32 Soho Square, W.

At the Court at Balmoral, the 20th day of November, 1873, present—The Queen's Most Excellent Majesty in Council.

Whereas, by an order of her Majesty in Council, dated the 7th day of November, 1868, her Majesty was pleased, under and by virtue of the provisions of the Medical Act, by and with the advice of her Privy Council, to re-nominate and re-appoint for five years from the 17th day of November, 1868, Edmund Alexander Parkes, Esq., Doctor of Medicine, Professor in the Army Medical School, Netley, and Richard Quain, Esq., Doctor of Medicine, of Harley Street, London, to be respectively Members of the General Council of Medical Education and Registration of the United Kingdom for England, and to re-nominate and re-appoint for a like period Robert Christison, Doctor of Medicine, Professor in the University of Edinburgh, to be a Member of the said General Council for Scotland, and to re-nominate and re-appoint for a like period William Stokes, Esq., Doctor of Medicine, Regius Professor in the University of Dublin, to be a Member of the said General Council for Ireland. And whereas, under and by virtue of the provisions of the said Act, the said Edmund Alexander Parkes, Richard Quain, Robert Christison, and William Stokes did, on the 17th day of November instant, respectively cease by lapse of time to be members of the said General Council. Now, therefore, her Majesty, by and with the advice of her Privy Council, doth, under and by virtue of the provisions in that behalf contained in the said Medical Act, nominate the said Edmund Alexander Parkes and Richard Quain to be again, from and after this 20th day of November inst., respectively Members of the said General Council for England, from and after the same date, James Warburton Begbie, Esq., Doctor of Medicine, of Great Stuart Street, Edinburgh, to be a Member of the said General Council for Scotland, and the said William Stokes to be again, from and after the same date, Member of the said General Council for Ireland, the said several nominations to continue for the term of five years from the day last aforesaid.

EDMUND HARRISON.

Dr. Andrew Wood then introduced—

Dr. Daniel Rutherford Haldane, who replaces Dr. Alex. Wood; Professor Wm. Turner, who replaces Dr. M'Robin; and Dr. James Warburton Begbie, who replaces Professor Christison.

Dr. Stokes introduced—

Dr. Rawdon Macnamara, who replaces Dr. Hargrave.

3. The President then proceeded to address the Council as follows:—

Gentlemen,—I congratulate you on your new abode. I trust that the Council at large will be satisfied with the way in which the Executive Committee has carried out the instructions “to obtain premises where the meetings of the Council may be held and the general business carried on with comfort and convenience.”

The result, which you see, has cost not only much time, but some trouble. A report on the subject will immediately be laid before you by the Executive Committee; and if any further information be desired, it will gladly be given by the treasurers or myself. I have thought it advisable that such

parts of my correspondence with the late Government as have not already appeared in the minutes of the Executive Committee, should be arranged and placed in the office, so that all that has passed with regard to this house can at any time be readily referred to. The terms on which the Council will hold the house are not so favourable as we had been led to expect, but if any member of the Council thinks that the Executive Committee might have done better, I will beg him to consider *all* the circumstances of the case, and to look at the answer of the then Government to the application of the Council, and to remember the actual pressing necessity in 1858 for providing a local habitation for the Council before we should lose the power of retaining even our insufficient accommodation in Soho Square. The letter from the late Government offering this house to the Council was dated the very day of their resignation of office. To one part of this letter I may refer with some gratification—that in which the Lords of the Treasury expressly recognise the claims of the Council to a certain measure of public assistance. These were the grounds on which the application to Mr. Lowe, for apartments, rent free, was made and urged. The claim was expressly disallowed in 1858. I am glad that now it has been however, partially admitted. It is not quite reasonable or fair that the cost of the work done by the Council should be wholly defrayed out of the registration fees paid by men entering our profession. The persons benefited by this work are not members of our profession alone or chiefly, but in a much higher degree the general public, for the chief purpose and end of our work is to prevent the entrance into the profession of persons in whose hands the health and lives of the public could not be safely trusted.

I believe—indeed I have no doubt—that to Mr. Lowe we are mainly indebted for the favourable terms on which this house was offered to us. If less favourable than we had reason to expect, they are yet not undeserving acknowledgment.

From the present Government we have received prompt courtesy. An application to the Treasury for a reasonable concession in regard to the date of the lease was answered by return of post, and the answer was favourable. To the officials of the Office of Works we are really under great obligations for their readiness in receiving suggestions for the requisite alterations in the building, and for the skill and activity with which these have been carried out. The building *was* a mere shell, wholly unfit for our needs. You will see what it now is, and can judge what it will be when all that is intended shall have been quite completed.

We are very greatly indebted to the good will and zeal and ability of the Office of Works, for all that they have done has been done, as it were, against time—in a very short period. And we are certainly not less indebted to our Treasurers, and particularly to Dr. Quain, who, as many of you know, has been, from first to last, the chief moving spirit in this business. But for him we could not possibly have met here to-day. But for the unsparing devotion of his valuable time to our service—his time by night as well as day—we might now, in this broiling weather, have been cooped up in the corner of Soho Square. We owe, also, not a little to his thoughtfulness and his taste.

But all this is well known to others besides myself, who are better able than I am to express adequately our thanks.

In opening the session of this spacious hall, I have one regret only—that *all* those who sat with us in Council last year are not here to-day. Four of them are absent. Sir R. Christison, whose words added weight to any debate—whose name has, for so many years, been known and held in respect wherever medicine is studied, representing as he does, in the highest degree, all that for which his University has long been famous. Alexander Wood, who, like Christison, was from the first a member of the Council, and whose great capacity for business, and equal or even greater gifts of oratory must have made him a marked man in any position in which he might have been placed. Macrobis—kindly, candid, honest, and able. I think it one of the many happy incidents of my connection with the Council, that it gave me his acquaintance and I hope his friendship. And we miss, too, the genial smile of our friend, Mr. Hargrave.

But our new colleagues must not think themselves less welcome because we do not forget their predecessors. We see in their presence that however great may have been any one of our losses, it is not too great to be replaced.

Since the last meeting of the General Council, the examinations of some of the medical authorities have been visited

and reported on. It would be superfluous for me to say much of these reports. They tell their own tales, and tell them with such manifest ability, as to require no commendation of mine. And they do more than convey information respecting particular institutions. They raise some question of a general kind, the discussion of which cannot fail to be serviceable to that which is our great object—the advancement of medical education and of the standard of acquirements in our profession.

But though I say no more than this of the reports themselves, I may be expected to make some mention of the arrangements of the Executive Committee for carrying out the visitations. In the selection of visitors regard was had to prior experience as examiners. Their number was purposely limited, so as to allow of one visitor inquiring into the examinations of more than one licensing body, and thus helping to guide us towards an equivalency of standards in parallel cases. I am sure that the Council will think the Executive Committee fortunate in having obtained the services of men so eminently qualified and whose statements and opinions are entitled to so much respect. By two gentlemen only were the invitations declined—by Dr. John Ogle and Mr. Teale, of Leeds; and in both cases with expressions of regret at their inability. We lost the valued services of Mr. Holmes on his appointment to the Board of Examiners of the College of Surgeons of England. His nice sense of propriety perceived an incompatibility in the two offices.

In all cases, when practicable, a physician and a surgeon were associated in the visitation.

No notice was given beforehand to the body about to be visited. The intention to visit was, I believe, in all cases kept secret.

The reports have not been subjected to any revision by the Executive Committee. In no case has even a single word been altered after the reports had been sent in. As to any instructions beforehand, none were given, except such as were needless in the case of such visitors. They were no more than that the reports should be thorough and unfettered—just what the visitors might observe and think for themselves.

Another work that has been done since our last meeting is the compiling and publication of the Additions to the *Pharmacopœia*. A report of the Pharmacopœia Committee will bring this under your consideration, and will, I doubt not, meet your approval.

Only a few words more—my last words I may call them—and pray, under the circumstances, forgive their egotism. Five years ago the Council did me the honour of electing me their President. This very day is the anniversary of my election, for I was elected on the 9th of July, at 6 p.m., or thereabouts. In a very few hours, therefore, my period of office will be at an end.

The honour bestowed on me five years ago was the highest I ever received—the highest I should ever care to receive. I am very conscious how small a return I have made for this distinction. But I have endeavoured to make such a return as you would most approve of, for I have tried to discharge my duties to the best of my ability. All honours have their responsibilities, and mine has been no exception. As President, I have been more responsible than any other member for the efficient discharge of the duties of the Council. And our joint responsibilities are not light; for they are of the same kind, and manifold more weighty than the every-day responsibilities of our profession. Like them, but in a larger sense, they are responsibilities to be measured by men's lives and men's sufferings. To raise and maintain a high standard of acquirements in those who enter our profession is our main duty here. To neglect this duty would be to let men die whose lives might be saved, to let men suffer whose health might be restored.

But in all responsibilities or difficulties, and amidst the many shortcomings of which I am sensible, I have always been sure of the support of the Council. Their kindness has never once failed me. During the entire five years of my office there has not been one single instance in which I have been treated otherwise than with the utmost kindness and consideration by all members of the Council, collectively and individually. I wish I could adequately express my gratitude.

Happily our responsibilities are limited by the extent of our powers, and by the proportion that our powers bear to the largeness and difficulties of our task. The powers given to the Council by the Medical Act are but slender. Its main

task, that of elevating medical education, is a large one. All great educational improvements are great tasks, and though ours be, in one sense, limited, being confined to one profession only, in another sense, it is very large, for its extent is the area of the whole United Kingdom. This is indeed a fact of which the Medical Council may well be proud. Our Council is, as far as I know, the only body, except the Houses of Parliament, of which both the constitution and functions are truly imperial, the only body in which English, Scotch, and Irish representative men meet together to consult upon and devise measures that shall be common to all three divisions of the kingdom. In this the Medical Council sets an example that may well be envied, and might with advantage be imitated. But in this, which may well be our boast, is also, it must be admitted, one of our difficulties. The improvements, to be effectual for this purpose, must proceed *pari passu* throughout the whole United Kingdom. And another impediment to rapid progress is, that our members, English, Scotch or Irish, are, and I would say must be, or ought to be, for the most part, practitioners of medicine—men therefore busy at home, and meeting perhaps only when assembled together in our annual session, bringing, therefore, greater diversities of opinion than might perhaps be found if their intercourse were more frequent.

But notwithstanding these obvious difficulties, and though time is found by experience to be a great and necessary element in all great educational improvements, though we have not hitherto succeeded in simplifying our work by reducing to a small number the nineteen separate sets of examiners, yet our success has not been discouraging when compared with our powers.

It may be, and doubtless is, difficult to estimate the progress that has been made, but at all events we know that a few years ago a man could enter our profession without producing any evidence whatever of general education. Now a preliminary education is enforced on all, and the proofs of this are given in almost all cases prior to the commencement of medical studies. The future influence of this on the social status of our profession can scarcely be overrated. We know that a few years ago only three or four of the licensing bodies made clinical examinations a part of their tests of fitness for a diploma. This test was even spoken of as objectionable. Now all the bodies insist on it. We know that a few years ago in the examinations for medical commissions in the army or navy it was not uncommon to find about forty per cent. of the candidates ignorant and incapable, though already in possession of diplomas both in medicine and surgery. Of late these discredit failures have become so few as to be almost, if not quite, insignificant. I am happy to say that on the very last occasion of examinations for army medical commissions, those of March, 1874, which will be laid before you to-day, there was *not one* of these failures. And surely the like signs of improvement are equally manifest *throughout* our profession. Teachers tell us so. Laymen have no doubt of it. Certainly my own experience is so. I know not a few young village practitioners whose acquirements might have placed them a few years ago in the foremost rank of practitioners in large towns.

I do not claim for the Medical Council *all* the credit of these improvements. Something is due to the admirable spirit for doing better and better which pervades our profession, and is kept alive by the medical journals. Some share of the credit may also fairly be given to the licensing bodies; *all* of them have improved their examinations, and some of them have set an admirable example and seconded this Council with a most praiseworthy public spirit.

May I venture to add, to what I have already said, that the limitation of our powers both in education and still more in other matters relating to our profession—that our difficulties and the degree of success actually attained by us have become better known to the profession at large than they were some five years ago; that it is now more clearly seen that the Council has not the same freedom of action as a voluntary association—that it cannot take part in all matters that concern the profession—that many such matters, however interesting and important to the profession, are altogether beyond or beside the functions of the Medical Council as defined by Act of Parliament, and that the Council is less obnoxious to blame than was formerly supposed, for want of energy in dealing with the licensing bodies.

Have we then in that which is our chiefest duty—the providing for the public the best possible medical advice—have we yet attained that happy standard of excellence at which

we may rest and be thankful? I am very far from thinking this. I am far from thinking that the actual state of things is *satisfactory*. Nothing, indeed, is *satisfactory* which admits of further improvement. That there is room for further improvement is not doubtful. But enough has been effected to encourage the Council in doing more.

It is true that the powers given to it by the Medical Act are slender, but it has an influence more ready and sure in its operation than the statutable coercive power, which could be exercised only through an appeal to the Privy Council, and which would probably fail, except in case of very plain dereliction of duty on the part of the offending body.

The chief power of the Council, as I believe, is that which it gave itself; when, on the motion of our friend, Dr. Andrew Wood, the Council determined that its debates should be *public*. The agency of the Press giving publicity to our debates and proceedings, has, I believe, more than doubled the power of the Council—doubled its power for anything that is right and reasonable—doubled and more than doubled its influence with the licensing bodies in any question in which this council may be in the right, and they in the wrong.

I have, therefore, no fear as to the future of the Medical Council. It has before it a course of usefulness, which I am sure will be followed with success.

Its main purpose is of the highest national importance. How this may best be effected will be for you to decide, and is not for me to indicate. It would be unbecoming for me to talk of what should be the work of the council in the coming time, when I shall no longer be a member of it. I shall look on, from a distance indeed, but with unceasing interest and with the respect which I have long learned to feel, and shall never cease to feel, for the Medical Council.

I will now resign my chair, and leave you to choose my successor.

Hereupon Sir James Paget vacated the chair he had for so long ably occupied, and retired from the Council Chamber.

On the motion of Dr. Wood, seconded by Dr. Aquilla Smith, Dr. Stokes was called to the chair.

Then it was moved by Dr. Storrar, seconded by Dr. Allen Thomson, and agreed to—

“That the address of the President be entered on the minutes.”

Dr. Andrew Wood stated that as one of the oldest members, having sat with Brodie, Greene, Burrows, and the retiring President, he had great pleasure in proposing the following resolution:—

“That the hearty thanks of the Council be given to Dr. Paget for the great courtesy, impartiality, ability, and success with which he has discharged the duties of President of the Medical Council.”

In seconding the motion of Dr. Andrew Wood, Dr. Aquilla Smith said he had particular pleasure in doing so. Dr. Paget's effective relation to the Committees was well known to him, and he was glad of the opportunity to thus acknowledge them.

Moved by Dr. Andrew Wood, seconded by Dr. Apjohn, and agreed to unanimously:—

“That Dr. Paget be re-elected President of the General Medical Council.”

Dr. Paget having retired not only from the chair and the Council Chamber, but also from the very building wherein he had recently exercised so exalted a position, a courier was despatched to convey to him the announcement of his re-election to the presidential chair, and from the delay the incident occasioned the difficulty of re-capturing him seemed very considerable.

In the interval Dr. Quain seemed anxious to press a resolution in reference to the diplomas on midwifery issued by the Queen's University in Ireland, although it was pointed out to him that Sir Dominic Corrigan, the representative at the Medical Council of that body, had not yet taken his seat. For the reason adduced, (*vide* the preliminary proceedings.)

At length Dr. Paget having returned to the Council Chamber, stated that he heard there was a message for him, and being told of his re-election to the presidential chair, resumed it amidst applause, during which he offered to the assembly in his usual kind and effectual manner a few trite words of thanks for the honour again bestowed on him, he regretted that at the close of the session he should retire from the Presidency.

The following committees were then appointed:—

## THE BUSINESS COMMITTEE.

Dr. Andrew Wood, Chairman. Dr. A. Smith, Dr. Leet, Dr. Haldane, Dr. Pyle.

Moved by Dr. Andrew Wood, seconded by Dr. Begbie, and agreed to:—

"That the Finance Committee consist of the following members:—Dr. Quain, Chairman. Dr. Bennett, Dr. Sharpey, Dr. A. Smith, Dr. Fleming.

The following report of the Executive Committee on the new premises for the Medical Council was then read.

## REPORT OF EXECUTIVE COMMITTEE AS TO THE NEW OFFICES OF THE COUNCIL.

In pursuance of the resolution of the General Medical Council of March 5, 1872, the Executive Committee have been in communication with the Government, as the Council are aware, for many months. After protracted negotiations they have at last succeeded in obtaining the premises in which the Council are summoned to meet, well known as formerly the Royal College of Chemistry. The terms on which the house has been granted have been made known to members of the Council by the minutes of the Executive Committee of February 23, 1874, to March 27, 1874.

They are, shortly stated, a lease of 31½ years, at a yearly rent of £300, the Government undertaking to expend £1,500 in adapting the building to the wants of the Council, and reserving a right of terminating the lease at the end of seven, fourteen, or twenty-one years.

It is estimated that the total annual expenses of the house, including the care of it, the rates, and all other charges, will not be less than £460. This should be borne in due proportions by the General Medical Council and the English Branch Council.

The latter Council resolved, April 2, 1874, that they will be prepared to contribute for their accommodation in the same proportion as they have hitherto done in Soho Square. This offer of the English Branch Council is very advantageous to the General Council, and the Executive Committee therefore recommend the Council to accept it.

If this arrangement be adopted, the annual expense chargeable to the General Council may be estimated at one-third of £460, i.e., £153 6s. 8d., which will have to be defrayed out of the percentage rate, and will therefore fall on the several Branch Councils, in proportions, which will vary a little from year to year.

Taking the percentage rate as it has been on the average of the last three years, the incidence of the expense of the house on the Branch Councils may be estimated as follows:—

The English Branch will pay—			
Two-thirds of £460	...	...	£306 13 4
Rateable proportion of £153 6s. 8d.	106 8 5		
			£413 1 9
The Scotch Branch will pay	...	...	21 16 0
The Irish Branch will pay	...	...	25 2 3
			£460 0 0

A considerable sum must also be expended in paying for the requisite furniture and fittings. The amount cannot be exactly estimated at present, but it is thought that it will not much exceed £500.

The Executive Committee regret that, notwithstanding the strenuous exertions of the office of works, the building is still in a somewhat unfinished state.

Moved by Dr. Andrew Wood, seconded by Dr. Begbie, and agreed to:—

"That the report of the Executive Committee on the new offices of the Council be received and entered on the minutes."

Moved by Dr. Storrar, seconded by Dr. Pyle, and agreed to:—

"That the General Council approve the arrangements recommended by the Executive Committee for the apportionment of payment by the Branch Councils of the rent, taxes, and expenses of offices, &c."

Moved by Sir William Gull, seconded by Dr. Sharpey, and agreed to unanimously:—

"That the thanks of the Council be given to Dr. Quain for his services in the negotiations and other business connected with the acquisition of, and furnishing the new premises of the Medical Council."

The following opinion of counsel respecting diplomas in midwifery, issued by the Queen's University in Ireland, and previously alluded to (see Minutes G. C., vol. x., p. 114), was then read:—

"We are clearly of opinion that the Medical Council cannot register the diplomas in midwifery granted by the Queen's University in Ireland."

(Signed) G. JESSEL.

CHARLES BOWEN.

The reports of visitations of examinations were then submitted to the Council.

And it was moved by Dr. Andrew Wood, and seconded by Dr. Parkes:—

"That the reports of visitations of examinations be received and appended to the minutes of the present session of the Council."

Dr. Storrar now rose and questioned the judiciousness of publishing these reports and feared it would lead to and give pain to many of the public. He acknowledged the importance of these visitations, consequently they should be chary in the matter. The function should be exercised by the Council in a friendly spirit, and received by the colleges in a like spirit. He considered these reports should be sent to the bodies to which they belonged, confidentially, and in the spirit of co-operation, and ask particular attention to them. The object should be to see when deficiencies and faults existed, and to correct where laxity existed. A few years ago a visitation of the London University led to suggest alterations which were subsequently acted on.

Dr. A. Wood supported his resolution, although he did not agree to many things in these reports.

Dr. Macnamara objected very strongly to their publication, he said it was not fair to an institution to speak of faults which do not exist, and in a particular instance. At the same time as the representative of one of the colleges visited he desired the fullest enquiry.

Dr. Quain was in favour of the resolution.

Dr. Fleming objected.

The President asked if these reports were to be discussed should they be discussed in private.

Dr. Storrar wished to show they should be discussed in private, if at all, but was told by the President he had previously spoken on the question.

Dr. Bennett suggested the reports be received as read, but not appear in to-morrow's programme.

Dr. Humphrey considered the report should be entered on the minutes.

Dr. Haldane, as representing one of the colleges visited, courted discussion.

Dr. Paget considered if the amendment was to be carried it would be difficult to have the matter discussed in public.

An amendment moved by Professor Turner, and seconded by Dr. Storrar was negatived; it was as follows:—

"That the reports of the visitors of examinations be received, but held for the present as confidential."

After a protracted discussion, in which Drs. Bennett, Humphry, Smith, Quain, Sir H. Corrigan, and others took part, it was

Moved by Sir W. Gull, seconded by Dr. Apjohn, and agreed to:—

"That the reports of the visitations of examinations be considered to-morrow in committee of the whole Council."

The following letter was then read:—

Dinsdale Park, Darlington,

Jan. 16th, 1874.

SIR,—I am requested to inform you that at a meeting of the South Durham and Cleveland Medical Society, which was held at Middlesbrough on the 7th inst., the members were unanimous in their opinion that the Medical Council was ineffectual for the proper protection of legally qualified medical men, and for the prosecution of those who are unqualified. It was also maintained that the General Medical Council was the most suitable body for undertaking public prosecutions under the Act.

I am, Sir, your obedient servant,

J. W. EASTWOOD, M.D., M.R.C.P.L.,

President of the South Durham and Cleveland Medical Society.

Moved by Dr. A. Smith, seconded by Dr. Acland, and agreed to:—

"That an extract from the Minutes containing the Report on Prosecutions adopted in 1859 (see Minutes G. C., vol. i., p. 35) be forwarded to Dr. Eastwood for the information of the South Durham and Cleveland Medical Society."

Two letters from the Assistant-Secretary to the Board of Trade were read respecting two registered practitioners who were

not allowed to take charge of emigrant ships in consequence of their misconduct, which consisted, it would appear, in having been intoxicated as the ships were about to leave harbour.

Moved by Sir D. Corrigan, seconded by Sir W. Gull, and agreed to :

"That the Registrar acknowledge the receipt of the letters and state that the Council have no power to interfere in the cases referred to."

Read—A letter from Dr. Walter Mackern, complaining of a registered practitioner lending his name illegally to a person unqualified.

Moved by Sir Dominic Corrigan, seconded by Dr. A. Smith, and negatived :

"That the Registrar acknowledge the receipt of the letter just read, and refer Dr. Mackern to clause XL of the Medical Act, which empowers him to proceed against offenders against that clause of the Act."

After a judicious and able argument in support of the complaint tendered by Dr. William Mackern, Dr. Macnamara proposed, and Dr. Leet seconded the following amendment, which was subsequently carried :

"That a committee be appointed to take Dr. Mackern's letter into consideration and to report to this Council at an early date."

The Committee to consist of—Dr. Macnamara, Chairman, Dr. Andrew Wood, Dr. Leet, Dr. Bennett, and Dr. Storrar.

Moved by Dr. Acland, seconded by Dr. Apjohn, and agreed to :

"That copies be obtained of the report of the Committee of the House of Commons on the adulteration of food : and further, that a Committee be appointed to consider the bearings of that report on the qualifications in 'state medicine' or in 'public health,' instituted by any of the bodies in Schedule (A) to the Medical Act."

The Committee to consist of—Dr. Acland, Chairman, Dr. Allen Thomson, Professor Turner, Professor Apjohn, Dr. Stokes, Mr. Quain, Professor Parkes, Sir Dominic Corrigan, and Mr. Bradford.

#### FRIDAY'S PROCEEDINGS.

To-day at one o'clock two special Council Committees assembled, one to take into consideration Dr. Mackern's letter, and the other to "consider the bearings of the report on qualifications in State Medicine or in Public Health instituted by any of the bodies in Schedule (A) to the Medical Act." The former consisted of Drs. Macnamara (Chairman), Wood, Leet, Bennett, and Storrar. The latter consisted of Drs. Acland (Chairman), Allen, Thomson, Stokes, Mr. Quain, Professors Parkes, Turner, Apjohn, Sir Dominic Corrigan, and Mr. Bradford.

Precisely at ten minutes past two o'clock the President resumed his chair, and the business of the General Council proceeded. The minutes of last meeting having been read, a desultory conversation amongst the Council arose as to the appointment of a surveyor for the recently acquired premises. Then the "tables showing results of examinations" were submitted.

Dr. Wood proposed—

"That the Council resolve itself into a Committee of the whole Council, for the consideration of the reports of visitations of examinations."

This was seconded by Professor Turner.

Sir Dominic Corrigan believed that not more than half of the licensing bodies permitted the presence at their examinations of the visitors of examinations. He was clearly of opinion the resolution should be deferred until a full and complete report from all the licensing bodies be received. A discussion followed in which the President, Drs. Quain, Wood, and others took parts. The motion was carried.

It was proposed by the President and agreed to—

"That the report on the examinations of the Society of Apothecaries of London, made by Dr. Quain, Dr. Barclay, and Mr. Busk, be taken as read."

Hereupon Dr. Quain addressed the Council on the merits of the report, dwelling with much force on the case of a candidate who had passed the College on the first anatomical examination, but, at the Hall examination he placed the spleen on the right side, then over the liver, and knew nothing whatever of cæcum and other viscera. He also alluded to the fact that the Society of Apothecaries had the power to confer its diploma on candidates without testing their knowledge of surgery.

An animated discussion followed in which many members of the Council took part, including Drs. Bradford, Thomson Sharpey, Bennett, the President, and Dr. Macnamara.

Dr. Andrew Wood believed the presumed faults alluded to by Dr. Quain were due not so much to the examination as to the ignorance of the candidate. He really questioned whether the early education of young men intended for the profession should not receive more immediately the attention of the Council. With regard to the remarks of Dr. Quain as to no surgical examination being required by the Apothecaries Company, he, (Dr. Wood) was of opinion that until candidates underwent a complete examination on all medical subjects their names should not be placed on the Medical Register.

Mr. Bradford having offered some explanatory remarks on the subject, introduced by Dr. Quain, it was moved by Dr. A. Smith, seconded by Mr. Quain, and agreed to :

"That a copy of the reports of the visitations of examinations be placed in the hands of the reporters now present at the meeting of the General Medical Council."

It was then moved by Dr. Quain, seconded by Dr. Pyle, and carried :

"That a copy of the report of the visitors of the examinations of the Society of Apothecaries be forwarded to the Society for their consideration and remarks."

Sir Dominic Corrigan much regretted the time that had been wasted on the discussion. They rejected his resolution, which was that a copy of the report be forwarded to the licensing bodies, and now in the special case of the Apothecaries' Company they actually agree to his proposition.

Dr. A. Smith, although not objecting to the motion, wished to say a few words on the subject. On reading the report he found the questions put under the several heads scarcely applicable to junior students. Hereupon he proposed the following resolution :

"That the question No. 4 (under the head of "Midwifery, &c.," in Report), "what are the symptoms, diagnosis, and treatment of *tabes mesenterica*," is not a proper question in an examination on midwifery."

Dr. Apjohn reviewed the chemical questions, and considered them, with the exception of the second, important indeed, but would suggest to the Apothecaries' Company to make them more practicable. He was about to move a resolution on the subject when Dr. Parkes stated that he considered a general resolution on the subject of these examinations at a future time more suitable to the purpose than a special one. To this suggestion the Council unanimously agreed, and the motion before the Council was withdrawn. Previous to this time it had been ascertained that the examination on midwifery alluded to included that on the diseases of children also, which accounted for the question on which Dr. Smith's resolution had been based.

The Council then resumed.

In the case of a registered practitioner summoned to attend an inquiry,

It was moved by Sir Dominic Corrigan and seconded by Dr. Storrar :

"That the Council having been informed, through their solicitor that a registered person who had been summoned to appear before the Council on this day had shipped for Adelaide, the summons for his attendance could not be served upon him."

Amendment, moved by Dr. Macnamara, and seconded by Dr. Parkes :

"That the case of the registered person be referred to the Branch Council of that division of the kingdom in which he is registered ; and that it be investigated, and if necessary, be dealt with in accordance with sec. 14 of the Medical Act."

The original motion was carried.

The Council again resolved into a committee of the whole Council.

Moved by Dr. Parkes, seconded by Dr. Apjohn, and agreed to :

"That the reports of the visitors of the first and second conjoint examinations of the Royal Colleges of Physicians and Surgeons of Edinburgh, held in July, 1873, be forwarded to the two Royal Colleges for their consideration and remarks."

A protracted conversational (yet rather warm) discussion, in which Drs. Bennett, Wood, Haldane, Sharpey, the President, Professor Turner, Drs. Apjohn, Storrar, Macnamara, Fleming, Humphry, and Quain took part, preceded the disposal of

the motion, during which frequent references were made to the official report of the visitors of examination.

It was now moved by Dr. Bennett, and seconded by Mr. Quain :

"That the report of the visitors of examinations for the single qualification of the Royal College of Physicians and Surgeons of Edinburgh be forwarded to those bodies for their consideration and remarks."

After a like discussion the motion was agreed to.

Moved by Dr. Parkes, and seconded by Dr. Apjohn :

"That the report on the second conjoint examination of the Faculty of Physicians and Surgeons of Glasgow and of the Royal College of Physicians of Edinburgh, held on the 15th and 16th January, 1874, be forwarded to the Faculty and to the Royal College for their consideration and remarks."

Dr. Fleming expressed his disapprobation with the report, especially at page 84. The remarks therein were quite uncalled for, and the facts of the case did not warrant them.

Sir Wm. Gull considered the College, that Dr. Fleming represented highly complimented in the report.

Sir Dominic Corrigan believed that the portion of the report alluded to did convey an innuendo, and did bear a double meaning.

Dr. Parkes stated the paragraph was placed there without intention; there might be, however, examiners and examinations not so competent as on the occasion of this visit.

In the discussion that followed Dr. Haldane, the President, Drs. Humphry, Storrar, and Turner took part.

Sir Wm. Gull was of opinion that teachers should not be the examiners of the students they teach, and he felt that the Council might prospectively bear this in mind.

Dr. Storrar believed the best examiners had been teachers themselves. In the University, if an examiner found his own pupil before him as a candidate, he uniformly handed him over to another examiner.

Mr. Quain considered there was great art in examination. It was far more difficult to examine than to lecture. He considered that to expect from a pupil of two sessions a thorough knowledge of chemistry, physiology, and anatomy was quite out of the question.

Dr. Fleming now stated that the 12th of August being grouse-shooting day—and if Scotchman loved one thing in the world more than another it was grouse-shooting—on that day the visitors to the examinations attended, and the circumstance accounted for shortcoming—if they really had any.

The resolution was carried.

Moved by Dr. A. Smith, seconded by Sir William Gull, and agreed to :

"That the report of the visitors to inspect the first and second examinations of candidates for the diploma of the Faculty of Physicians and Surgeons of Glasgow be forwarded to the Faculty for their consideration and remarks."

Dr. Bennett submitted to the Council some remarks on his visit (in connection with Mr. Busk) to the examinations of the Royal Colleges at Edinburgh. In the course of the discussion which followed it was ascertained that the report did not state the results of the examinations, nor had mention been made by the visitors in the report of the passed or the rejected. In page 79 of the Visitors' Report of Examinations it is stated "The answers to these questions we did not receive."

During a discussion it was elicited that the papers were not refused, but that Dr. Bennett and his colleague did not find amongst the papers received from the College certain answers to questions that appear in the report. Dr. Smith inquired if these papers were refused. Dr. Bennett replied in the negative. Dr. A. Wood considered the note in the report seemed to cast a slur on the College, although, as the College has been always most willing to submit the result of their examinations to the Council, he considered Dr. Bennett and his colleague should have written to the authorities of the College on the subject. Dr. Bennett felt justified in taking the whole blame of the matter, the blame did not rest with the College.

Dr. Wood was dissatisfied also that the number of passed and rejected candidates were not mentioned in the report.

Mr. Quain considered we ought to be slow to shut men out of the profession by rejecting them at a first examination. Out of every 600 that went in for a first examination not more than 400 ever went in for the fourth, and the consequence was that people of small means could not get practitioners at a price, and had to seek gratuitous medical aid.

It was now moved by Dr. Quain and seconded by Dr. Humphry :—

"That a copy of the reports of the visitors to the several examinations of the University of Glasgow be forwarded to the University for its consideration and remarks."

After some remarks by Dr. A. Smith, Dr. Allen Thomson rose and reviewed the report issued by the visitors of examination. He explained the mode of examination, the number of questions given to each candidate, and the number of marks necessary to constitute a "pass mark." He agreed with Mr. Quain, that the difficulty of teaching was greater than of lecturing, and he also held that there was great difficulty in, and experience required by the gentlemen deputed to act as visitors of examination. On behalf of his colleagues, he might say they were prepared to entertain any suggestions the General Council might favour them with.

Professor Turner referred to the second paragraph in page 123 of the Report, and stated that it did not apply to the case of the University of Edinburgh. In the case of the University of Edinburgh theses have to be submitted, and in some cases candidates are rejected, and do not receive their M.D. qualification on account of the imperfection of the thesis productions. In the University of Edinburgh very many subjects are required to be known not insisted on by other colleges—the examination is most testing—written, *viva voce*, and practical.

The President reviewed the remarks made by Dr. Allen Thomson, and Professor Turner, and then explained the mode adopted at Cambridge and London.

Sir William Gull stated that for four and twenty years he was a teacher at Guy's; it was a sheer pretence to put down a standard on figures. One of the best pupils he ever had was brought to the bed-side of a patient to write out the clinical history of a case; it was a case of hysteria in a woman: his report was correct, but he got but the second place. In the University of London clinical examinations were introduced at an early date, and at Guy's Hospital before also.

The President explained that the University of Cambridge examined clinically as early as the year 1842, and gave a particular instance where such examination had taken place at about that date.

Dr. A. Smith now moved, and Professor Turner seconded :

"That the reports of visitations of the examinations for 'Letters Testimonial' of the Royal College of Surgeons in Ireland be forwarded to that College."

Dr. Macnamara, on behalf of the College he represented, returned his sincere thanks to Dr. Smith and to Mr. Henry Power for their impartial report. He entered into a concise and eloquent review of several portions of the report, taking up the paragraphs *seriatim*, and making special allusion to the operations on the dead subject performed by the candidates. He also replied to the complaint made by the visitors of examination (*vide* report), which stated the written papers of candidates were denied to them. He explained that the papers of candidates for the licence of the College, as a rule, were uniformly torn up, and thus destroyed immediately after being read by the examiners. In the cases of candidates for the Fellowship, the reverse obtains. He concluded his most able address by pointing the attention of the Council to correspondence on the subject which passed between the authorities of his College and visitors of examination, as *vide* Report, pages 145, 146.

A discussion on the subject followed, in which Drs. Wood, Fleming, Parkes and others took part.

Sir William Gull now rose, and stated that, having read over the report of the visitors of examination, he considered the Irish College of Surgeons was just then in a very unsatisfactory state. Several paragraphs in the report were such as to question whether a special vote of censure ought not to be passed; they were there to do their duty, and he for one would perform it. Sir William Gull having read to the Council paragraphs of the report, moved the following amendment to the former resolution. This amendment was seconded by Dr. Parkes :

"That the Council has had its attention drawn to the many sources of imperfections in the examinations conducted for Letters Testimonial of the Royal College of Surgeons of Ireland, and trust that the accompanying reports of the visitors at those examinations will receive serious attention on the part of the authorities of the Royal College. And that in any future visitation the written papers of the candidates may be preserved and submitted without restriction to the visitors."

Dr. Smith bore testimony to the facts in the report submitted by himself and his colleague.

Dr. Macnamara complained of the fact of Sir W. Gull having skipped over paragraphs in the report favourable to the Irish College, but placed in a strong light before the Council paragraphs unfavourable to the Irish College of Surgeons. He again explained to the Council the opportunities offered by the College to the visitors to see the papers alluded to, as he before stated. One of the informalities complained of arose from the visitors to examinations having arrived a day after a portion of the examinations of candidates had been proceeded with. Dr. Macnamara read to the Council several paragraphs of the report, which went to show that Sir William Gull's amendment was entirely uncalled for, being based on wrong deductions, drawn by him from the report of visitors to examinations, as the report clearly and distinctly showed. No positive good could or would arise from such a proceeding as Sir William Gull originated. The Council of the College of Surgeons in Ireland knew their duties to this Council, to the profession, and to the public, and from the beginning had determined to do it fully and conscientiously. The visitors of examination state all this in their report, and it is quite out of his power to comprehend the object aimed at by the amendment proposed.

Sir Dominic Corrigan rose, and felt convinced the Council were drifting into the position he had seen from the first, that is, they were casting allegations against one of the licensing bodies. Anything like this should not be attempted, and decidedly not until first shall be received by the Council reports from all the Colleges. Charges were now made against the College of Surgeons in Ireland, and he contended that no resolution should be passed, but if it were yet determined on, the answer to the charges made against that body should be first received.

The amendment was carried, and put as a substantive motion.

Thus moved by Sir William Gull and seconded by Dr. Parkes :

"That reports of the visitors on the examinations of the Royal College of Surgeons of Ireland be forwarded to the College for its consideration and remarks.

"The Council has had its attention drawn to the many sources of imperfections in the examinations ; and trust that the accompanying reports of the visitors will receive serious consideration on the part of the authorities of the Royal College, and that in any future visitation, the written papers of the candidates may be preserved and submitted without restriction to the visitors for perusal."

Thus ended Friday's proceedings.

#### SATURDAY.

Previous to the adjournment of the Council on Friday evening, an arrangement was entered into for this day's sitting. It was to commence at one o'clock and to close at four o'clock. By the time the hands of the unpretentious-looking dial, the mechanical representative of stern old Time, placed in a puncture made in the wall on the left side of the President, and exactly above and behind the seat Sir Dominic Corrigan so efficiently occupies, pointed to the hour fixed on, the President and nearly all the members of the Council were in their places, and the proceedings of that august body were resumed.

The minutes of Friday's sitting having been read, revised, and agreed to, Dr. Aquilla Smith invited the attention of the Council to the remarks of Mr. Quain on the standard of medical education required by the licensing bodies at the present time, and moved :

"That the Council resolve itself into a Committee of the whole Council."

Dr. Storrar seconded the motion.

The adjourned consideration was resumed of the reports of visitations, and the following motion by Dr. A. Smith, seconded by Sir William Gull, was submitted to the Council :

"That the report of the visitors to inspect the first and second examinations of candidates for the diploma of the Faculty of Physicians and Surgeons of Glasgow be forwarded to the Faculty for their consideration and remarks."

Dr. Macnamara considered the report of the visitors of examination on the Faculty of Physicians and Surgeons,

Glasgow, a most important one. The mode by which candidates for that qualification were examined was extremely faulty, and required to be at once rectified. That qualification was regarded as a surgical qualification more than as a medical one, yet from an examination of the report, it would appear that the candidates were not examined on the dead subject, no surgical instruments were exhibited before them in order to test their knowledge of them ; no pathological specimens were shown, nor, still less, was there any surgical test insisted on by the examiners. A five minutes' examination on physiology too could not by any possibility be considered a sufficient one. At one time the Irish College of Surgeons had a *viva voce* examination only, but experience proved that many candidates for the licence, who had never ungloved their hands within the precincts of a dissecting-room, presented themselves before the examiners, and in some cases apparently displayed sufficient knowledge to satisfy the examiners of the time as to their fitness to receive the licence. Now, however, all that has been changed. The candidate for the diploma of the Irish College of Surgeons is obliged to handle his scalpel, and to show his familiarity with and his dexterity in using it. On the dead subject his operative powers are tested by this method, and the examiners are at once able to see and to note the full value of the candidate. Dr. Macnamara bore testimony to the great improvements made in the method of examination and the education of students. In justice to the College he represents, to the Council, and to himself, he could not permit the report of the visitors of examination to pass without calling attention to the several matters on which he had dwelt, and he sincerely hoped that for the cause of medical education, and for the credit of the licensing body itself, he hoped that in future a better mode of examination would be pursued, and the knowledge of candidates tested in the practice of surgery. With regard to the relative value of *viva voce* and written questions, the former he believed to be the better mode of testing the knowledge of candidates ; set questions were often written, he feared, not so much to be answered as to make a display, and to show the erudition of the examiner. Then again, he was sorry to say that candidates rejected at one college very often received the diploma of some other within a few days of such rejection. Until a measure be adopted to check this state of affairs he believed the Council would ever find themselves engaged in the discharge of a useless and a fruitless task.

Dr. Macnamara illustrated his remarks on this part of his subject by giving the case of a candidate who had been rejected on three occasions by the Irish College of Surgeons, and whose name appeared in the registration roll as having obtained double qualifications within a few days from the date of his rejection. In another case, a student received a Scotch diploma immediately after his rejection by the Irish College, and, remarkable to relate, on the registration roll his name was entered as if the candidate obtained the licence of the very licensing body that rejected him. In reply to several members of Council, Dr. Macnamara stated that he did not wish to give names, but the facts were as stated, and if the Council, after giving the cases some consideration, still persisted in pressing him for these names he would be prepared to give them.

Sir Dominic Corrigan regretted extremely the second case had been mentioned ; long, long ago the irregularity in registration alluded to had been explained away ; it was simply a clerical error performed by those whose duty it is to make the record in those cases. The gentleman alluded to deserved, and should have obtained from the Irish College of Surgeons, the qualification he sought, and which was a mere formality, nevertheless, necessary in order to meet a contingency. Not having obtained it from the Irish College, he sought it, and secured it too, where best he might. He was a most distinguished pupil. (Sir Dominic Corrigan here entered into minute particulars of the case, giving names and stating circumstances we do not think, in justice to the gentleman alluded to, we should reproduce.)

Dr. Apjohn felt perfectly justified in stating to the Council the gentleman alluded to was a remarkably distinguished student.

In the discussion that followed, the President, Drs. Storrar, Bennett, Parkes, Smith, and others took part, at the close of which Sir Dominic Corrigan again rose and said that some persons were of opinion that the names of rejected candidates ought to be sent to the nineteen licensing bodies ; for his part he could not agree to this ; were the Council to

entertain the matter for a moment they should be lowering themselves to the position of insurance companies, who send the names of rejected applicants for insurance to each other.

Dr. Wood energetically defended the Scotch College against the charge made upon them. In all cases where candidates came before the licensing bodies there such candidates received from the examiners their just deserts. Candidates from Ireland and from other places came before the Scotch examiners and received from them their kind, impartial, deliberate, and just consideration which in very many instances they should have received at home, and which probably had been denied them there.

Professor Turner wished to know if the Irish College of Surgeons, as a rule, asked the candidates coming up for examination whether they had been previously rejected by any other college.

Dr. Fleming defended the Faculty of Physicians and Surgeons of Glasgow. He referred to page 99 of the Report of Visitors of Examination. For his part he was aware of cases where candidates rejected at Glasgow obtained Dublin diplomas. Dr. Fleming asked the attention of the Council to several sections of the Report in order to show the extent and searching ordeal adopted by the Faculty of Physicians and Surgeons of Glasgow to test the extent of medical and surgical knowledge candidates for the qualification should possess to entitle them to receive it.

#### MONDAY, JULY 13TH.

Sir Dominic Corrigan having been summoned by a committee upon Mr. Errington's Bill at the House of Commons was unable to be present at the Council meeting at the time our reporter left. The adjourned consideration of reports of visitations of examinations was therefore again adjourned, it being understood that Sir Dominic was anxious to make some remarks with reference to the Queen's University before the reports passed the Council.

The returns from the Medical Department of the Army, dated respectively September 8th, 1873, and March 4th, 1874, was the first business of the day. The following are the official returns :—

STATEMENT of the Degrees, Diplomas, and Licences of the Candidates for Commissions in the Medical Department of the Army, who in August last presented themselves for Examination, showing the number that passed, and did not pass, distinguishing the Qualifications, both Medical and Surgical, under the several Licensing Bodies, dated September 3rd, 1873.

	No. of Qualifications.		
	Total.	No. passed.	No. failed.
Royal College of Physicians, London	2	2	...
Ditto Surgeons, England	4	4	...
The Society of Apothecaries, London...	1	1	...
Rl. College of Physicians, Edinburgh	2	2	...
Ditto Surgeons, Edinburgh ..	2	2	...
K. & Q. Coll. of Physicians, Ireland	3	3	...
Royal College of Surgeons, Ireland ...	4	3	1
Apothecaries' Hall, Dublin .....	1	1	...
Queen's University of Ireland .....	2	2	...
University of Aberdeen .....	2	2	...
Trinity College, Dublin.....	1	...	1
University of Aberdeen M.B.	2	2	...
Queen's University of Ireland M.D.	2	2	...
Rl. Col. Surgeons, Edinburgh M.D.	1	1	...
Trinity College, Dublin M.B.	2	2	...
University of Edinburgh M.Ch.	1	1	...
Ditto ditto M.B.	1	1	...
<b>Total .....</b>	<b>33</b>	<b>31</b>	<b>2</b>

The total number of candidates was 15, 11 of whom succeeded in obtaining appointments ; 3 succeeded in examination, but not in obtaining appointments, there being only 11 vacancies ; 1 was rejected from the R.C.S.I., he being deficient in surgery.

The following are the official returns from the Navy Medical Department :—

STATEMENT of the Degrees, Diplomas, and Licences of the Candidates for Commissions in the Medical Department of the Army, who in February last presented themselves for Examination, showing the number that passed, and did not pass, distinguishing the Qualifications, both Medical and Surgical, under the several Licensing Bodies, dated March 4th, 1874.

	No. of Qualifications.		
	Total.	No. passed.	No. failed.
Royal College of Surgeons, Ireland ...	8	8	...
K. & Q. Coll. of Physicians, Ireland	5	5	...
Royal College of Surgeons, Edinburgh	4	4	...
Ditto Physicians, Edinburgh	3	3	...
Royal College of Surgeons, England...	2	2	...
Queen's University, Ireland .....	4	4	...
University of Dublin .....	1	1	...
Apothecaries' Hall, Dublin .....	1	1	...
University of Edinburgh M.Ch.	1	1	...
Ditto ditto M.B.	2	2	...
Queen's University of Ireland M.D.	5	5	...
University of Dublin M.B.	2	2	...
<b>Total .....</b>	<b>38</b>	<b>38</b>	<b>...</b>

Of the total number of candidates (18), all passed ; 16 succeeded in obtaining appointments ; and 2 succeeded in examination, but not in obtaining appointments, there being only 16 vacancies.

It was then moved by Dr. Apjohn, seconded by Dr. Parkes, and carried—

“That the returns from the Army Medical Department be entered on the minutes, and that the thanks of the Council be forwarded to the Directors General for the same.”

Dr. Andrew Wood wished to congratulate the Council upon the improved state of medical education. From the reports which were now presented from the two departments by Her Majesty's Service it would be seen that out of 15 candidates for Army medical appointments, only one was rejected ; whilst of the 18 candidates for the Navy, all passed. The Council concurred in Dr. Wood's expression.

The correspondence of Dr. Mackern, of Long Eaton, near Nottingham, complaining of the illicit practices of a certain quack, and of a certain duly qualified practitioner lending his name to quackery, was referred to the Branch Council of England on the motion of Dr. Macnamara.

The case of John Permewan, who had been some time since struck off the Register, but who now protested under advice of counsel against such an act, sought, through the Royal College of Physicians of Edinburgh, reinstatement to his former position as a member of the medical profession. The correspondence was simply read, the Council passing no opinion thereon.

A letter from the Registrar of the University of London, enclosing a communication from the Home Office respecting conjoint examination, was then read, and on the motion of Dr. Storrar, seconded by Sir Wm. Gull, the communications were ordered to be inserted on the minutes.

The motion of Dr. Aquilla Smith

“That a committee be appointed to prepare a new edition of the British Pharmacopoeia, to be ready for publication in January, 1877,” was negatived, as was also a motion “that the publication of the Annual List of Registered Medical Students be discontinued.” With reference, however, to the latter, the President remarked that Dr. Smith's inquiries showed clearly that the List was capable of improvement, and should be published earlier in the year, so as to obviate the objections raised by Dr. Smith.

A petition from Mr. John Joseph Ray, Licentiate of the Colleges of Physicians and Surgeons of Ireland, for permission to alter his name on the Medical Register, by the addition of an “e” to his name, was the occasion of a slight passage of arms between Dr. Andrew Wood and the representatives of the colleges concerned. The matter was afterwards referred to the Branch Council for Ireland, to satisfy the Council of the identity of the applicant before acceding to his request, the question resolving itself into a change of name, and not an error of the College at which he registered.

**"SALUS POPULI SUPREMA LEX."****WEDNESDAY, JULY 15, 1874.**

## GENERAL MEDICAL COUNCIL.

THE Session of the Medical Council for 1874 opened last Thursday, and the debates will probably continue to the end of the week. We give in this number a report of the proceedings up to the time of going to press, and here we propose merely to offer a few comments on some of the points that have been discussed.

First of all, we may congratulate the profession that Dr. Paget has consented to act as President for this session. He has filled the chair with so much ability and dignity that everyone has felt satisfaction, and we trust his successor may be equally fortunate in upholding the honour of the office. Who that successor shall be we hope the Council will decide at the close of the present session, so that he may have full time to prepare for the work of presiding during the long interval before the next sitting. We have heard rumours, like others, respecting the probable choice; but we do not deem it our business to repeat them, still less to offer suggestions. The Council has always given satisfaction in its choice, and will of course act independently.

In the course of his address, Dr. Paget paid a well-deserved compliment to the former members who have been replaced; and though we miss them much, like the President, we are prepared to find the new members bring vigour and wide information to the discussions.

Dr. Paget also congratulated the Council on the new premises in which the meeting for 1874 was held. Next year it will give more satisfaction, for it is not nearly completed. We hope the damp walls may not injure the health of members; but verily there seemed to us a serious risk of this calamity.

The most important business of all was perhaps the visitation of examinations. The report of the visitors filled a considerable volume, and will furnish matter for comment for a considerable period. Nothing can be much clearer than that the standard is very unequal. Of course we all knew this. It is natural that more than a score of corporations should conduct their examinations variously. There may be good and bad points in all the plans; but the cry for conjoint boards has been greatly supported by the desire to have a fair standard every-

where prevailing. This is the great purpose for which the public demands examinations, and certainly ought not to be lost sight of.

The returns from the army are very satisfactory, and strongly support the President's statement that great improvement has of late years taken place in medical education, for which the Council may fairly claim some credit, though we believe there has been a desire on the part of all the boards to stimulate progress, and medical teachers in all our schools have been zealous in the good cause.

We have already spoken of Sir D. Corrigan's new Bill. It would add one more to the already too numerous examining boards. If we are to have a State Board at all it ought to be passed first of all, but the corporations seem afraid of that. Assuredly to place it as Sir Dominic does, after a double qualification has been secured, is "to put the cart before the horse."

Dr. Aquilla Smith's proposal for a new Pharmacopœia at the end of a decade from the former issue is well-timed and important, and we were glad he suggested that the Pharmaceutical Society should be invited to co-operate. There can be no doubt far too much money has been squandered on the Pharmacopœia, and the cost of the chemical department has been inexplicable. Years ago we pointed out the extravagant manner in which this work had been accomplished, but it was worth a good deal to secure a national codex. The wretched little volume of additions issued this year appears to have been produced in the same costly manner, and is practically useless. There are scarcely any formulæ in it worth printing, and it is obviously useless to be always tinkering at a work of this kind. We hope the next Pharmacopœia may cost little and suffice for a longer period. The discovery of a new drug does not render such a work obsolete, nor require additions to be printed. If the Council were determined to print such additions, they would have conferred some benefit by printing them in such a way that each could have been bound into the old copies at its proper place; but really no one wanted the bantling of 1874, and we look upon its cost as so much waste.

The publication of the List of Medical Students is of little use; but there are occasions on which it is desirable to know whether persons so describing themselves have been registered. The Council has not taken pains to circulate the List, nor has it done all it might to make its List the only one. The London College of Surgeons still compels students to go to them. Students should refuse.

## THE EXAMINATIONS OF THE IRISH COLLEGE OF SURGEONS.

THE examinations of the London Apothecaries' Hall, the Glasgow and Edinburgh corporations, the Irish College of Surgeons, and the Queen's University in Ireland have come under the criticism of the visitors appointed last year by the General Medical Council, and the result of their observation of the methods adopted by these bodies was laid before the Medical Council last week in the form of a volume of more than 250 pages, a much more valuable contribution to medico-educational literature than any which the predecessors of the visitors have given to the

profession. The important portion of the contents of these voluminous reports may be easily epitomised, because five-sixths of the entire book is occupied with the examination questions and the replies of candidates, and with a description of the method of examination pursued by each body. We pass, for the present, over the verdict pronounced upon the Scotch corporations and the Glasgow University in order to refer to the report upon the examinations of the Irish College of Surgeons and the Queen's University in Ireland, and in that which refers to the former of these bodies we find abundant subject for the consideration not only of the Fellows of that College but of the surgical profession in Ireland.

It has been a tradition of half a century, in which Irish surgeons have maintained an unwavering belief, that the examinations of the Irish College of Surgeons have been and are more stringent and comprehensive than those of other bodies, and that the College—by a praiseworthy fastidiousness and by a meritorious sacrifice of financial interest—has thus maintained in the Irish School of Surgery the high standard of excellence which its previous achievements had won for it. It will be a rude shock to this belief in the pre-eminence of surgical education to learn that the visitors of the Medical Council have unqualifiedly condemned the system of examination still in force in the College as utterly insufficient both in time and method for the proper testing of candidates.

The visitors initiate their observations by the following remark :—

“The examination we were directed to attend was stated to commence on Tuesday, 13th January, 1874, at 3 p.m. We found, however, to our regret that an important part of the examination, that namely in dissection, had taken place on the previous day. We were informed that every student had been required to dissect for about half an hour, and on examining the subject we found that the vessels, nerves, and muscles of the axillary space on both sides, as well as those of the right side of the neck, had been fairly made out, and that the skin and superficial fascia of the inguinal region and upper part of both thighs had been reflected.

“We were given to understand that the performance of actual dissection by the candidates was an innovation, and was preparatory to certain improvements in the examination about to be adopted by the Council; but that the candidates had always been expected to recognise the parts displayed in recent dissections and in moist preparations.”

We conceive that the visitors had either been misinformed or had misapprehended the statement as set forth in the foregoing paragraph, for we are quite aware that until within the last few months the present examination by dissection was brought into operation, the candidate had not been subjected to any direct practical test whatever as to his anatomical knowledge.

Having minutely described the method of examination and of registering the marks, the visitors say :—

“In reviewing the conduct of this examination, several points appear to be worthy of comment. In the first place, we have no hesitation in saying that the time occupied in the examination should be considerably extended. A sufficient interval of time should intervene between the written and the oral examination to allow the examiners to read over carefully, and to assign a definite number of marks to the written answers. On the present system this is impracticable, since the oral commences immediately after the written examination is completed, and any time spent by the examiner in reading over the written answers must necessarily be deducted

from the time that should be spent on the oral examination; a matter of no small importance when only fifteen minutes is allowed for the latter.

“It is to be observed that the candidates who present themselves for this examination are students who have completed their *third* year of attendance upon lectures and dissection. They may, therefore, reasonably be required to give evidence of the possession of a thorough practical knowledge of anatomy, and of something more than mere elementary knowledge of physiology.

“We are of opinion that two written questions on anatomy and one on physiology do not afford a sufficiently searching test of a candidate's knowledge of these important subjects, even when supplemented by an oral examination of thirty minutes by two examiners, and would recommend that a more systematic method of examination should be adopted, several questions being given on each subject, and the candidates being allowed a sufficient time to reply to them.

“In regard to the oral examination, the questions were practical and good, and such as every well educated student should have been able to answer promptly and fully, whilst much kindly consideration was shown to the candidates; but we cannot avoid stating that, in our opinion, the quarter of an hour system of examination at successive tables is not well adapted for adequately testing the acquirements of the candidate, especially if he be astute, timid, or obtuse. The candidate needs only to be slow in answering, and it is impossible for the examiner to go much beyond the surface in the few questions he has time to put, and no opportunity is afforded of ascertaining, by pressing the questions, whether the candidate's knowledge is the result of a cramming system, or whether he really understands what he has read and seen.”

The visitors then refer to what is known as the “second half”—the surgical, or passing, portions of the examination :—

“In reporting upon the examination in operative surgery, to call attention to the advisability of the examiners submitting their questions to each other, or to the chairman, prior to the examination.

“In the present instance it will be seen that out of the five operations required to be performed, four were amputations. In three out of the four the candidates selected the circular method, and as they were all called in at the same time, it was easy for the less informed candidates to obtain hints and suggestions for their operations from the proceedings of others, and the incidental remarks of the examiners.

“We are of opinion that in addition to the advantage of preventing the improper acquirement of knowledge in this way, confusion would be avoided, and the examination would be altogether more satisfactory if one student only were called in at a time.

“On the present occasion, three candidates were operating simultaneously on the same subject.

“In one or two instances various questions were put to the candidates sufficiently testing their knowledge of operative surgery, but in other instances we are of opinion that this part of the examination was insufficient, and the operations the candidates were called upon to perform were not, in all instances, completed. We noticed, for example, that the candidates were not called upon to take up and tie the vessels or adopt any other measure by which hæmorrhage might be arrested, nor were they required to dress the stumps.”

The visitors then proceed to refer to the clinical examinations, upon which they express the following opinions :—

“No questions were asked as to the various methods of treatment that might be adopted, nor as to the result that might be anticipated, though all the cases seemed to us to afford a fair opening for such inquiries.

"No bandaging was required, nor were the candidates called upon to show the mode in which fractures should be put up or dislocations reduced.

"In these respects there can be no doubt that this part of the examination could be made very much more searching and complete, whilst by their omission the most important means at the disposal of the examiner for ascertaining the extent and accuracy of the practical knowledge possessed by the candidate and of the attention he has paid to his hospital studies were lost."

The visitors sum up their impression of the whole examination for the Letters Testimonial in the following words :—

"In conclusion, we may remark that the good points of this examination are sufficiently obvious. If efficiently conducted, it is difficult to conceive that any candidate could pass who had not acquired a thorough knowledge of the foundations of professional attainments.

"Its defects, on the other hand, as at present conducted, are no less patent; and we have the less hesitation in referring to them since we have reason for believing that they are recognised by several members of the Council, and are likely to be in part removed by changes about to be adopted.

"No one of the branches of the examination appeared to us to be fully carried out, and this essentially results from the circumstance that, notwithstanding three days are nominally devoted to it, the whole examination is conducted in too hurried a manner. The students are hurried in writing their replies to the questions in the written examinations, and the examiners are hurried in reading them; whilst insufficient time is devoted to the clinical and operative parts of the examination, in neither of which is more than a quarter of an hour devoted to the examination of each candidate."

We are incapacitated by the pressure upon our space, and the late hour at which the report of the visitors reached us, from commenting upon their verdict as fully as its importance deserves.

It may be satisfactory, however, to them and to the General Medical Council to be assured that these strictures upon the examination of the Irish College of Surgeons will be pronounced by the one voice of those who are acquainted with the system to be well deserved. It is a matter of notoriety that the examination, as at present conducted, is incapable of excluding an ignorant candidate, and unsafe for a well-educated and competent student. Nay, more! it is notorious that candidates who have proved the high order of their talents and education have been more than once rejected at the Irish College of Surgeons in consequence of the meagreness of the opportunity afforded them to prove their competency, while students with little industry and less knowledge have been permitted to receive the licence of the College.

#### MISS JEX-BLAKE AND HER EXAMINERS.

It is a remarkable fact, to which we have the almost unanimous testimony of those gentlemen who have, as the phrase runs, "been referred to their studies," that no student ever suffers plucking because of his ignorance or stupidity.

We know by the earnest assurance from each that he is the unhappy victim of uncontrollable circumstances, or of a foul conspiracy—that he has succumbed either to his adverse fortune or to the atrocious malignity or gross incompetency of the examiners, or to the flagrant faults

of the system of examination, but with the disastrous event neither idleness nor incapability have anything to do.

It seems that the medical sisterhood of plucked students are no more ready than the Bob Sawyers of the day to acknowledge that their sentence is just, and that their idleness righteously punished, for we find that their higher intelligence is not superior to the nurture of the same delusive ideas which animates the unlucky "sawbones" under similar circumstances.

Miss Jex-Blake has not been as happy in satisfying the examiners of the University of Edinburgh as she may consider herself to have been in persuading the public that she is the persecuted advocate of a holy cause. She has been—let us whisper low as we utter the ignominious participle—"stuck," and, what is worse, the melancholy truth has not been permitted to remain unnoticed, for an ardent friend was good enough to assure the public that she would have passed but that her public duty as an agitator had made the preparation for her examination "a secondary consideration." But Miss Jex-Blake was not of the stuff to suffer defeat and tamely apologise. She writes to the *Times*, roundly asserting that, in her opinion, her preparation was "thoroughly adequate," but that as the examiners could not be punished for her "alleged" failure she had—with great magnanimity—consented to allow the matter to rest. This letter elicited a reply from the examiners briefly to the effect that the lady's papers were unanimously voted to be "extremely defective on every subject," and Professor Huxley, to whom the papers were shown by a friend of Miss Jex-Blake, distinctly and unhesitatingly confirmed this verdict.

It has been already abundantly evident that discretion is not the better part of Miss Blake's valour, and in this transaction both she and her friends have manifested a degree of imprudence and undiscipline of temper which does not testify favourably to their self-control. There is no significance whatever in the rejection of a female medical student, more than that of her male analogue, and no one need experience surprise or found any conclusion upon one failure of the sort; but there really is in the thirst for newspaper publicity of Miss Jex-Blake and her friend an eloquent illustration of that absence of discretion and hastiness of judgment which is vulgarly attributed to Miss Blake's sex, and which cannot be considered a desirable attribute in anyone who seeks for success in the thoughtful and solemn rôle of a physician.

#### Royal College of Surgeons of England.

THE annual meeting of the Council of the College of Surgeons was held on Thursday, the 9th inst, when the newly-elected councillors took their seats. The annual election of officers took place, when Mr. Le Gros Clark was elected President, and Sir James Paget, Bart., and Mr. Prescott Hewett, Vice-Presidents for the ensuing year. Mr. Henry Lee was elected Professor of Surgery and Pathology, Mr. W. K. Parker Professor of Comparative Anatomy and Physiology, and Mr. Erasmus Wilson was re-elected Professor of Dermatology.

## Literature.

## BAZAAR MEDICINES. (a)

DR. WARING has been long and favourably known to the profession by his various contributions to medical literature, especially to therapeutics, and the highest compliment that could be paid to his abilities in this department was done when he was appointed editor of the Indian Pharmacopœia—a work of considerable research, and possessing information that could only be found elsewhere with much difficulty.

From what we gather from the preface, the present work would appear to have been written more for missionaries than the profession, and consequently we shall be guided in our criticism of the work rather by the uses it is intended for them than as a strict and accurate description of all those bazaar medicines which are daily prescribed by Indian medical officers, and approved of and set down in the Bengal medical regulations. The "introduction" possesses no feature of novelty—it is the old stereotyped advice and directions which have been written in *secula seculorum* in every medicine-chest companion. Part I. contains an alphabetical list of bazaar medicines and Indian medical plants, together with their uses. The only drug amongst the A's is Atis, or Atees, which we think English practitioners might try; it is inexpensive, and has in our hands proved efficacious both in intermittent and other periodical fevers.

The next important drug is the Bael Fruit, and certainly we think a more extended trial of it in England would lead to its becoming a fashionable medicine. We have tested it on a very large scale in India, especially in diarrhœa and the earlier stages of dysentery, with the happiest results, and practitioners in England who have much to do with Anglo-Indians will find this medicine or fruit valuable in chronic dysentery and hæmorrhoids; and lastly, as Dr. Waring truthfully observes, "in irregularity of the bowels, presenting alternations of diarrhœa and constipation, taken early in the morning, often exercises a most beneficial effect." In this section we notice some valuable native drugs are not alluded to. "Chaulmûgra" is a medicine of such importance in leprosy that we are surprised to find so very meagre a description, especially as missionaries would be likely to see more of this distressing malady than medical men; and no allusion whatever is made to Dr. F. T. Mouat's valuable paper on this drug.

"Chiretta," Dr. Waring says, "is a good bitter tonic, and, when procurable, renders the practitioner in India independent of imported articles of the same class." In our hands chiretta has proved something more than this, as we have found it to have an almost specific action on the liver, especially in the engorged liver of the newly-arrived European, in the milder forms of congestion so commonly met with in Anglo-Indians who have long resided in notoriously malarious districts, and especially have we regarded it as a *sine quâ non* when treating Anglo-Indians who have retired from the service, and who may be suffering from atonic dyspepsia, &c. We trust Dr. Waring's allusion to the probability of not being able to obtain this drug is imaginative rather than real, as in our day every bazaar in India was well supplied with it.

Kala-Dana, or black seed, is an excellent purgative, and when in India, we prescribed it both for Europeans and natives, and found it in all respects as safe and certain a purgative as jalap.

Kamela has (as the author correctly observes) attained considerable repute as a remedy for tape-worm. When prescribing it for natives we have met with a fair percentage of success, but not sufficient to regard its action as specific, and from clinical observation were soon led to discard it for Europeans, substituting for it oil of male

fern, which in our hands never failed to bring away the worm entire.

Mudar, which bears the same relation to ipecacuanha that Kala-Dana does to jalap, is well worth a trial, and we should be glad to find the Dreadnought Hospital trying some of the remedies we have incidentally mentioned, and thus giving this institution more of the tropical character it obtained in the days of Dr. Geo. Budd.

If space permitted, we might perhaps draw the attention of our readers to some few other native drugs; but we have said enough to show the general character of this part of the work. It is good and clear, but the descriptions are too short; many native drugs of acknowledged value are omitted; the bazaar prices are not given, and all, or nearly all, reference to contemporary writers is omitted.

Part II. is an index of diseases, which will prove useful to missionaries.

Appendix A contains directions for restoring the apparently dead from drowning. All the natives that we have ever met, with one solitary exception, could swim.

Appendix B does not give a practical interpretation to the motto "*Audi alteram partem*," in that it merely contains "reprinted by permission from Dr. Fayer's splendid work," a summary of his treatment of persons bitten by venomous snakes without the slightest allusion to the writings, experiments, and discoveries of Dr. Halford, of Australia, and the very excellent little pamphlet of Dr. Butter, late of Bengal.

In conclusion, we have no doubt for missionaries Dr. Waring's book will prove useful, and we trust that by doing so they will hereafter confine themselves to their sacred calling rather than add another to the list of wars they have already created in Burmah, New Zealand, and Abyssinia.

## DOMETT STONE'S THERAPEUTICS. (a)

THIS is a book which will interest some readers very much, and others very little; it consists of the opinions of leading authorities, British and foreign, on the treatment of various diseases, arranged alphabetically. The man of extensive reading may not care much to look over a summary of this kind, but younger practitioners who have not read widely nor witnessed the practice of different schools will be pleased with the judicious selection of medical opinions compiled by Dr. Stone, who has had experience in selecting when editor of the lately discontinued Half-Yearly Abstract. In this volume he has applied that experience to collect from books of permanent value the salient points of treatment advised by their authors. He does this with much skill, and though in reading a good deal of it we met with no opinion with which we were unacquainted, we are convinced that there are many practitioners who will be glad to compare the views of authorities, and they may safely trust to Dr. Stone's book, for we find it accurate. Then there are a good many references, and perhaps these might be advantageously increased. Dr. Stone may also, perhaps, in future make an effort to trace the original source of some of the recommendations. One thing comes out very strongly in this book—the diversity of opinion amongst able men in reference to the value of remedies. A casual reader taking it up for half an hour may well exclaim "Who shall decide when doctors disagree?"

## THOROWGOOD'S MATERIA MEDICA. (b)

THIS is the third volume of a new series of small text-books, of which the two former have already been reviewed in our columns, and of which it is a worthy companion. It is no small praise to say that Dr. Thorowgood has

(a) "An Epitome of Therapeutics." By W. Domett Stone, M.D., F.R.C.S. London: Smith, Elder, and Co. 1874.  
(b) "The Student's Guide to Materia Medica." By J. C. Thorowgood, M.D., Physician to Victoria Park Hospital; Lecturer on Materia Medica at the Middlesex Hospital. London: J. and A. Churchill. 1874.

(a) "Bazaar Medicines." By E. J. Waring, M.D. London: J. and A. Churchill. 1874.

produced a manual of materia medica that may vie with Dr. Fenwick's "Diagnosis" in usefulness to the student. There are many works on materia medica of varying degrees of merit and of various sizes. Judging this by the intention for which it is produced, none is superior. It presupposes the possession by the student of the British Pharmacopœia, and therefore does not repeat the formulæ and directions of the official volume, but it gives an account of the chemical composition of medicines, the processes by which they are prepared, their reactions, uses, and doses.

The additions to the Pharmacopœia published this year are also briefly noticed, as well as the process of volumetric analysis. In going through the book we have been several times struck with the manner in which it is brought down to date, and with which the many facts are compressed into a small compass.

Thus, we have on page 140, croton-chloral hydrate, and on the next page amyl nitrite, both recent additions to our materia medica, finding which, we looked for other novelties in the index, almost always with success. Propylamine is referred to in two places, but has not obtained a paragraph for itself. There is a better account of oxygen than in any other text-book, and the same may be said of phosphorus, aconite, and some other medicines that have recently been talked about. Of course, it would be unfair to compare the book in some respects with much larger works; but for a small manual it is excellent, and we congratulate the author on his success.

#### TROPICAL DEBILITY. (a)

PRACTITIONERS in this country are often at a loss how to vary their treatment in the presence of the marked debility that is the too constant result of a residence in tropical countries. For this purpose we took up with considerable interest Mr. Dickinson's new pamphlet, and we find it contains a number of valuable hints and wrinkles that should make it welcome to all. As a long resident in India, who has also served throughout the Crimean campaign, and in other parts, Mr. Dickinson is well qualified for the task of imparting his knowledge of the effects of hot climates on the constitution of Europeans, and as he has now been some years in England, he is also able to give sound advice respecting the care needed for patients on their return to England. As an example of how much Mr. Dickinson can compress into a small compass, we take the following extract:—

"It cannot be too forcibly impressed on the reader's mind that in treating the Anglo-Indian our endeavour is to build up and strengthen the shattered constitution by every legitimate means, and that when restored, the liability to a recurrence of such ailments as chronic dysentery, ague, neuralgia, eczema, and many others, is all but impossible. The general outline of treatment can only be indicated here. As before observed, in every case it will be necessary for the medical adviser to consider the condition of the Anglo-Indian on his return from the tropics under two heads—viz., his general condition, which is one essentially of debility, and his special condition, which is evidenced by various manifestations of disease.

"The subjoined classification I have found useful as an aid to diagnosis:—

"a. Impoverished condition of the blood, and the diseases connected therewith.

"b. Nervous affections, as evidenced by loss of memory, insomnia, preternatural excitability and paroxysmal mania the result of sun-stroke, neuralgia, loss of virility, impotence, and spermatorrhœa, mental depression, numbness, sciatica, and certain forms of skin diseases, especially eczema, and not infrequently psoriasis.

(a) "Tropical Debility: a Treatise on the Causes and Treatment of Debility produced by Prolonged Residence in the Tropics." By James C. Dickinson, late of H.M. Bengal Medical Staff, and formerly Staff-Surgeon Crimean Expeditionary Army. London: Baillière, Tindall, and Cox.

"c. Dyspepsia, together with the functional and organic diseases of the organs of digestion.

"d. Obesity, emaciation, chronic dysentery, chronic diarrhœa, congestion of the spleen, and congestion, inflammation, and abscess of the liver.

"e. The diseases of women, especially leucorrhœa and irregular menstruation, and many other affections of the womb which have been hinted at or referred to in the body of the work."

## Correspondence.

### THE HARVEIAN ORATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg leave to request the insertion of the accompanying letter in the MEDICAL PRESS AND CIRCULAR.

I do so because its subject concerns the ethics of medical journalism as well as because I feel some explanation of the publication of the Oration in the *British Medical Journal*, even before it was in the hands of all the Fellows of the College of Physicians, necessary to my own justification.

I am, Sir,

Your obedient servant,

61 Wimpole Street, London, W.

CHARLES WEST.

TO THE EDITOR OF THE BRITISH MEDICAL JOURNAL.

SIR,—It is with much surprise that I see the Harveian Oration delivered by me on June 27th, and published by Messrs. Longman and Co., reprinted *verbatim* in the *British Medical Journal*.

A copy was sent to you, as editor of that journal, as to others, by my publishers, for such notice as it might please you to take of it.

Permission to print it had already been asked by yourself as well as by the editors of other journals, and refused by me, believing as I do that the course which I adopted of printing and circulating the Oration among the Fellows of the College was more respectful to the body to which I have the honour to belong than to leave it to be read in the pages of any journal, however influential.

There are certain courtesies which are so common that one never deems it possible they should be forgotten, certain rules of morality so elementary that society could not exist without them. It appears that on this occasion you have had the misfortune to forget both.

It will be an ill-day for the medical profession when those who affect to direct its tone ignore the ordinary rules of every-day life, and from critics descend to become literary freebooters.

I am, Sir,

Your obedient servant,

CHARLES WEST.

I beg leave to inform you that in justification of myself I have sent a copy of this letter for insertion in the other medical journals as well as in the *British Medical Journal*.

### IRISH POOR-LAW MEDICAL OFFICERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I received the following letter from our county member in reply to my application requesting him to support the interests in Parliament of Irish Poor-law medical officers, including the whole payment of their salaries by the State, instead of half, as at present, thus making them to a certain extent a branch of the Civil Service, whereby promotion, increase of salary according to length of service, and certain superannuation would take place, &c.

G. BOLSTER, M.D.

Newcastle, Co. Limerick.

[COPY.]

House of Commons, Thursday night.

MY DEAR DOCTOR,—I am in receipt of yours, together with the enclosures. I shall be very glad to support the amendments, if proposed, both in the Coroners and the Public

Health Bills, as I consider them only just and fair, and as stated in papers which you enclose. As to getting an amendment in the Irish Poor Law this year, there is no chance, as the business of the House is overcrowded, and one-half of it won't be got through.

I remain, my dear doctor,

Faithfully yours,

WM. H. O'SULLIVAN.

G. Bolster, Esq., M.D.

### PHARMACY IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Leet is reported to have said that about thirty towns in Ireland, with a population of from twenty-eight to thirty thousand, were without an apothecary. If this is the case, we must have Bigman's portion in the county of Cork, as I know of no town in the county with a population of a thousand, with the exception of one, that has not at least one. Cork has 13, Bandon 3, Kinsale 4, Mallow 4, Fernoy 2, Kanturk 2, Macroom 2, Middleton 2, Queenstown 2, Charleville 2, Bantry 1, Dunmanway 1, Youghal 1, and even Skibbereen is not without one, and has had two in my recollection. That makes 40 in one county. Besides this number there are a good many L.A.H.'s living in country districts who have not shops. I should say, taking all in all, there are at least 50 in the county. So much for Dr. Leet's statistics as applied to Munster.

Yours truly,

A PHYSICIAN.

### ESTIMATION OF TOTAL NITROGEN IN URINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Permit me to offer a short reply to Dr. Austin's letter in your issue of the 1st instant.

Dr. Austin, in his former letter, supposed that I had overlooked the fact, well known to chemists, that the soda-lime process does not necessarily give the total nitrogen in organic bodies. I replied by pointing to my preliminary treatment of urine with sulphuric acid as being specially directed and sufficient to meet the difficulty, and reminded Dr. Austin that the only step beyond is the "absolute" method of Dumas. I took it for granted that a "medical analyst" could not require any further explanation on so simple a matter; nevertheless, Dr. Austin now regards my remarks as "quite irrelevant," and supposes I "completely passed over without comment" his objection. I shall now leave him to a further study of this point.

Dr. Austin also objects to my plan of "Nesslerising" as being unreliable for quantitative work with small amounts of ammonia; but in reference to this it is only necessary to say that the difference in developed tint between the 9-1000th and the 10-1000th of a grain of ammonia is recognised with facility, in order to show that the plan possesses even more than the requisite delicacy.

So far for Dr. Austin's criticisms on my plan; but he also takes exception to my selection of Liebig's process for estimating urea alone in urine, and he appears to be indignant that I should not have recommended Dr. Davy's chlorine process instead. It would have given me great pleasure for many reasons to do this, if it were possible; but the process referred to does not possess the requisite precision. On the other hand, Liebig's I know to be the best yet proposed for the purpose. In my last letter I dwelt as little as possible on the objections to Dr. Davy's process, as I did not wish to make any unnecessary statements respecting it. Dr. Austin, however, has misinterpreted my motive, and now considers my remarks as "mere assertion without proof." If Dr. Austin will kindly turn to the *Chemical News* for June 12, 1874, he will find more than sufficient proof, for he will there see that not only did Dr. Davy himself find that his treatment gave less than the true amount of nitrogen from urea, but that Huffer, even when using the more manageable hypobromite, ascertained the loss of nitrogen to be irregular and to reach 6 per cent. Dr. Russell, of London, also estimated the loss at about 8 per cent.—a quantity rather greater than the whole proportion of "residual nitrogen" I had to deal with. Knowing these matters well long before the remarks appeared

in the *Chemical News*, and believing the plan to be a "rough and ready" though interesting process, it would have been absurd for me to give it the preference to Liebig's valuable method, however much I might desire to acknowledge the work of a countryman.

Dr. Austin's zeal has been rather in excess of his discretion in this matter, and, as the discoverer of a new urea myself, and therefore of necessity peculiarly familiar with the reactions of these bodies, I may suggest to him to study their characters and those of allied bodies more closely before giving a strong opinion as to the merits or demerits of a process for urea estimation.

I am, Sir, your obedient servant,

July 3, 1874.

J. EMERSON REYNOLDS.

### PRACTICE IN AMERICA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Enclosed I send my half-yearly subscription for 1874. I never paid money more willingly for any literary medical journal than I do for the *MEDICAL PRESS*. I consider it instructive and tasteful, imbued with the spirit of this wonderful age, and opposed to that self-conceit which wishes for no change.

Having resided for many years in that part of North America termed the Western States of the United States, although that country is greatly divided since the wretched Civil War, and likely to continue so, I had a fine opportunity of seeing diseases almost unknown to the British Isles (from their peculiar malignity), and am at a loss to know how young inexperienced men manage after having received appointments. As to the class of men who simply go to better themselves, they, as a matter of course, instinctively see their deficiencies, and begin to learn, though, in many instances, they find their first principles almost of no practical value, and fall into American views and mode of practice.

The American medical men, springing from a quick-witted race, are able in the treatment of diseases peculiar to their climate, although they labour under many serious disadvantages, being sadly off (comparatively speaking) for the want of such eminent medical schools as are to be found in London, Dublin, and Edinburgh, as also the noble hospitals of these cities, supervised by medical men of the greatest ability and humanity, as they invariably are; they are not protected by the law, contending with bare-faced itinerant quacks, who ply their infamous trade most successfully on a people who do not drink deep of the Pierian spring, but take for granted all the vain assumptions of these fellows, who pretend to cure all diseases incident to humanity. Yet such is their great perceptive powers, their ardent love for their noble profession, their thirst for knowledge, being all reading men, that, as a profession, they stand high in the estimation of the country. Besides, they have produced such men as Valentine, Mott, and writers like Eberle, Gross, Tully, *cum multis aliis*.

I noticed the total disuse of the lancet, the large quantities of quinine, morphine, podophyllin, and many other alkaloids used, whilst mercurial preparations are avoided as much as possible. As to diseases, they assimilate themselves to the seasons of the year. In the intense cold of winter grave attacks of pulmonary affections, termed congestions of the lungs, which have a rapid and fatal course, acute rheumatism, and neuralgia, assume the character of an endemic. This was the case in the last winter. Rheumatism assailed people of both sexes; no age was exempt, and *infants at the breast* suffered. In the winter of 1872 cerebro-meningitis was most prevalent and fatal at a place called Prairie du Chien, about ninety miles from where I resided, and a curious circumstance occurred which came immediately under my own observation. A present of baby-clothes was sent by a family resident in Prairie du Chien to a house where I attended, and shortly after the parcel was opened and examined by some of the children one of them was attacked with this disease (unknown in the neighbourhood) by terrible sickness, and all the violent premonitory symptoms of a dangerous disease. She recovered after four months' attendance, if recovery it can be called, but with total loss of memory of all her education, even to her very letters, besides the want of power of her left forearm and leg. Another, a younger sister, finally succumbed, after a struggle for months; and there were a few cases which occurred in the neighbourhood—some fatal and more not.

Dysentery is sure to make its appearance during the hot

term—very severe some summers, and not so much so occasionally, dependent, I think, on the range of temperature. In 1857 it became an epidemic, and carried away numbers. It was most unmanageable, and only terminated in the death of those attacked; and on examination the large intestines were nothing more than ulcerated shreds. Another scourge that every summer sweeps away thousands of infants is vulgarly termed the "summer complaint," but recognised by medical men as "cholera infantum." What is it? The most experienced men meet it with fear and trembling. The symptoms on invalids are immediate prostration, thready pulse, pallor, cold clammy sweat, rejection of aliment along with dejections of a gelatinous-looking substance with a reddish tinge. These cases terminate fatally, and often sweep away a whole young family, and leave a sad hiatus instead.

I hope you will excuse this letter, and I remain,

Yours truly,

E. N. HEATH.

Baltinglass, July 2, 1874.

### THE PATHOLOGY OF THE ARTERIES IN BRIGHT'S DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Campbell Black reiterates his misconception of the views of Dr. Geo. Johnson on this matter in so curious a manner as to suggest the idea of what theologians called invincible ignorance. He apparently is unable to recognise the distinction betwixt "thickening of the coats of blood-vessels" and "hypertrophy of their muscular tunic." Other people can recognise the distinction, and I trust Dr. Campbell Black will some day learn it.

As to the "curious mis-statement" that Dr. Johnson's view is "that the abnormal condition of the blood causes spasm of the minute arterioles of the kidney," it is another evidence of Dr. Campbell Black's inability to expound Dr. Johnson's views, for Johnson expressly asserts that the arteriole spasm is general, and not simply renal. I certainly must recommend Dr. Campbell Black to make himself somewhat acquainted with Dr. Johnson's views ere presuming to subject them to hostile criticism, as it is only too obvious that he does not understand Geo. Johnson's views as expounded by Dr. Johnson himself.

As to his saying, "I rather fear that Dr. Johnson cannot be congratulated on Dr. Milner Fothergill's defence of his opinions," it is simply another evidence of the obliquity of Dr. Campbell Black's mental vision. It may tend possibly even to shake Dr. Black's confidence in his acquaintance with Dr. Johnson's views to know that Dr. Johnson has written to me thanking me for putting his views so clearly.

The question now at issue is, whether is Dr. Johnson himself or Dr. Campbell Black better acquainted with the views of Dr. Johnson? Finally, Dr. Campbell Black raises a dark smoke, and then complains that he cannot see; he misrepresents Dr. Johnson's views, and then criticises his own misrepresentation.

I am, Sir, yours very truly,

J. MILNER FOTHERGILL, M.D., M.R.C.P.Lond.

Lower Seymour Street, London, W.,

July 10th, 1874.

### Gleanings.

#### Dr. Andrews on Ozone. (a)

SOON after the discovery of ozone, Schönbein having observed that the air of the country frequently coloured a delicate ozone test-paper in the same manner as ozone itself, inferred that ozone is a normal constituent of our atmosphere. He concluded that the amount of this body present in the air is different in different localities, and in the same locality at different times, and with great boldness he attempted to connect its presence or absence with the prevalence or rarity of certain catarrhal affections. A new field for investigation was thus opened up, which

has been assiduously cultivated by a large and zealous band of observers. Before referring, however, to their labours, it will be necessary briefly to allude to the present state of our knowledge regarding the existence of ozone in the atmosphere.

Schönbein always maintained that ozone is a constituent of atmospheric air, and his various papers on this subject would, if collected, fill a large volume. In his last memoir he observes that the active substance in the air acts in a parallel manner on iodide of potassium and suboxide of thallium papers, although more slowly on the latter; and that the thallium paper, which has been coloured brown by the air, behaves towards reagents in the same manner as that which has been exposed to artificial ozone. From these facts he infers that the active substance in the air is neither peroxide of nitrogen nor sulphuretted hydrogen. He further states that the atmosphere never contains free nitric acid, although nitrate of ammonium in small quantities is frequently present; and that neither chlorine nor bromine can be present in the free state in air, on account of their affinity for hydrogen. Houzeau also maintained that the existence of ozone in the air was proved by the alkaline reaction of iodide of potassium paper, which had been decomposed by exposure to the atmosphere. Although experiments and arguments of this kind were sufficient to give probability to the view that the active substance in the atmosphere which produces these reactions is ozone, they were at the same time far from conclusive; and some of the ablest chemists in Europe accordingly considered the question doubtful, while others attributed the effects observed to the presence of oxidising agents altogether different from ozone. I will only cite on this point the opinion of M. Frémy, whose researches in conjunction with M. Bequerel on ozone have already been referred to. "Without denying," he remarked at a meeting of the Academy of Sciences in 1865, "the importance of the indications given by the paper of M. Schönbein, or by that of M. Houzeau, I do not find that these reactions demonstrate with sufficient certainty the existence of atmospheric ozone. I am of opinion that the presence of ozone in the air must be established anew by incontestable experiments."

In 1867 I made a set of experiments which I had contemplated some years before, for the purpose, if possible, of finally settling this important question. These experiments have since been successfully repeated by Dr. C. Fox.

The identity of the active body in the atmosphere with ozone we may now assume to be established beyond dispute, and the accuracy of Schönbein's views on this subject to be fully confirmed. To determine, however, the actual amount of ozone in the atmosphere is a problem of surpassing difficulty, on account of the extremely small proportion in which it exists, even when at a maximum. Its presence can be easily discovered by any of the ordinary iodised starch papers, or even more readily by white bibulous paper which has been moistened with a dilute solution of iodide of potassium, and allowed to dry spontaneously in a dark room. If a slip of this paper be exposed for five minutes to a current of air, which will be often supplied by the wind, or may be produced by walking briskly, it will be found to have acquired a delicate red tint, if ozone be present even in the smallest quantities. The tint will be best observed by comparing the slip after exposure with another slip of the same paper which has not been exposed. The action of the diffused light of day on the paper is rarely perceptible after so short an exposure, but this source of error can be easily avoided by enclosing the paper in a hollow cylinder of wood.

Although, with the experimental resources now at our command, we can scarcely venture even to estimate the actual amount of ozone at any time present in the atmosphere, yet it may be possible, as Schönbein long ago proposed, by applying a chromatic scale to the indications of the test papers, to ascertain approximately its relative amount in different localities, and its variations in the same locality. Such estimates must, however, be most uncertain, since the shades of colour produced on test paper hardly admit of being defined by numbers; and in this particular case they are liable to a special source of error, as there can be little doubt that a large but unknown part of the ozone in the air which comes into contact with the paper is catalytically destroyed, and produces no chemical effect whatever. At the same time the ozonometer, especially

(a) Abstract of an address delivered before the Royal Society of Edinburgh.

when used with an aspirator, does unquestionably give indications of value regarding the ozone state of the atmosphere; and till more accurate methods are devised these observations ought certainly to be continued.

Ozone is rarely found in the air of large towns, unless in a suburb when the wind is blowing from the country; and it is only under the rarest and most exceptional conditions that it is found in the air of the largest and best ventilated apartments. It is, in fact, rapidly destroyed by smoke and other impurities which are present in the air of localities where large bodies of men have fixed their habitation, and I have often observed this destructive action extending to a distance of one or two miles from a manufacturing town, even in fine and bright weather.

Ozone is rarely, if ever, absent in fine weather from the air of the country, and it is more abundant, on the whole, in the air of the mountain than of the plain. It is also said to occur in larger quantity near the sea than in inland districts. It has been found to an unusual amount after thunderstorms—a fact which is favourable to the view that the presence of ozone in the atmosphere is due to the action of the free electricity of the latter on the oxygen of the air. The amount of ozone in the air is greater, according to some observers, in winter than in summer, in spring than in autumn; according to others, it is greater in spring and summer than in autumn and winter. As regards the influence of day and night, the observations do not all tell the same tale. Ozone has usually been found more abundantly in the air at night than by day, but some careful observers have found the reverse of this statement to be true.

Schönbein was the first who attempted to connect the fluctuations of atmospheric ozone with the prevalence or absence of epidemic disease; and since this suggestion was first published, numerous observations have been made in different countries with the view of ascertaining whether there is really any connection between the indications of the ozonometer and the health of a district. It has been asserted, for example, as the result of observation, that an outbreak of cholera is accompanied by a marked diminution of atmospheric ozone; but this statement has been disproved by later and more trustworthy observations. On the whole, I think it may be safely asserted that no connection has yet been proved to exist between the amount of ozone in the atmosphere and the occurrence of epidemic or other forms of disease.

The permanent absence of ozone from the air of a locality may, however, be regarded as a proof that we are breathing, if I may venture to use the phrase, adulterated air. Its absence from the air of towns, and of large rooms even in the country, is probably the chief cause of the difference which everyone feels when he breathes the air of a town, or of an apartment, however spacious, and afterwards inhales the fresh or ozone-containing air of the open country. It is, indeed, highly probable that many of the most important actions, by which the products of vegetable and animal waste are removed by oxidation from the air, are due to the action of ozone, and could not be effected by ordinary or inactive oxygen. If the amount of ozone in the atmosphere appear too small to produce such large results, we must remember that, from its powerful affinities, ozone is being continually used up, and must, therefore, be constantly renewed.

The physiological action of ozone on the animal system is a subject of interest, and I am able to state the general results of two independent inquiries—one conducted a few years ago, by Dr. Redfern, in Queen's College, Belfast, the other recently communicated to this Society by Mr. Dewar and Dr. McKendrick. Dr. Redfern's experiments have not been published, but he has kindly supplied me with the following note on the subject:—"The general results," he says, "I obtained from about forty experiments conducted from May to September, 1857, to find the effects of oxygen and ozone on different animals, are as follows:—The respiration for a very short time of oxygen, containing about  $\frac{1}{15}$ th part of ozone, is certainly fatal to all animals. The same gas, when passed over peroxide of manganese and freed from ozone, is comparatively harmless, even when respired for long periods. Respiration of such a mixture of ozone for thirty seconds kills small animals, some dying after respiring it only fifteen seconds; whilst similar animals will live in good health for months after respiring oxygen alone for thirty-seven hours, the carbonic acid being removed during the experiment. Death is not due to the closure of the glottis, for it occurs when a large opening

has been made in the trachea. Ozone causes death by producing intense congestion of the lungs with emphysema, and distension of the right side of the heart with fluid or coagulated blood, frequently attended by convulsions. If ozone be respired in a dilute form, the animals become drowsy, and die quietly from coma, the condition of the lungs and heart being the same, except that the emphysema is less marked. Animals which have respired oxygen for more than twelve hours will now and then die suddenly from the formation of coagula in the heart, even after they have appeared in good health for some days."

The following are the conclusions which Dr. Dewar and Dr. McKendrick have deduced from their researches: Inhalation of an atmosphere highly charged with ozone diminishes the number of respirations per minute, and reduces the cardiac pulsations in strength, the temperature of the animal being at the same time lowered from  $3^{\circ}$  to  $5^{\circ}$  C. After death the blood is found to be in a venous condition. Neither the capillary circulation nor the reflex activity of the spinal cord is appreciably affected. The same remark applies to the contractility and work-power of the muscles. Ozone acts on the coloured and colourless corpuscles of the frog like carbonic acid. Ciliary action is not affected by ozonised air or oxygen, but if the layer of liquid be very thin, the cilia are readily destroyed.

The thermal changes which accompany many of the reactions of ozone are well marked, and their investigation, which has been undertaken by Mr. Dewar, promises to yield a valuable addition to our thermo-chemical knowledge.—*Nature*.

#### The Hereditary Transmissibility of Progressive Muscular Atrophy.

By DR. EICHHORST, Königsberg.

THE author reports from Naunyn's clinic the case of a family in which muscular atrophy was hereditary. In six generations ten persons were affected successively. Of these, seven from three generations are still alive. These are the descendants of two sisters whose father, grandfather, and great grandfather were subjects of the disease. Five of the ten patients were of female sex, and many of the male members of the family, not affected with this disease, died early. The disease always began in the legs and, as a rule, only showed itself after puberty. The patients did not come under treatment until a comparatively late period. The ten cases are detailed in brief.—*Schmidt's Jahrbücher*, March 16th, 1874.

## NOTICES TO CORRESPONDENTS.

### SPECIAL NOTICE.

THE Publisher will be glad to receive arrears of subscription for last and previous years. He regrets to state that there are still several gentlemen against whose names there are as many as four and five years' arrears standing, and who have had repeated applications for payment by letter made to them without any response. He thinks such should not be the case in an honourable profession.

**ARMY MEDICAL DEPARTMENT.**—An examination of candidates for commissions in the Medical Department of the Army will be held in London on August 10th. Applications for admission must at once be made to the Director-General of the Army Medical Department.

**NAVY MEDICAL DEPARTMENT.**—A competitive examination for appointments in this branch of Her Majesty's Service will also be held on August 10th. The necessary forms and information will be supplied on application to the Director-General of the Department.

**MEDICAL COUNCIL.**—The Council is now located in its new offices, at 315 Oxford Street, W., a building formerly occupied by the Royal College of Chemistry. Applicants for registration or other business must address Dr. Hawkins, the Registrar, at the new address.

**A RELIC OF WATERLOO.**—The *Sussex Express* states that Dr. Harding, of Wadhurst, has successfully extracted a French musket bullet from the hand of James Jenner, weighing over three-quarters of an ounce, which was firmly embedded in him at the battle of Waterloo. In spite of the inconvenience arising from the bullet during nearly 60 years the man has worked uninterruptedly as an agricultural labourer in the parish, where he bears an excellent character.

#### VACANCIES.

East London Hospital for Children. Assistant Visiting Physician. Election August 4th. Particulars may be obtained of the Secretary. (See Advt.)

Cancer Hospital, Brompton. House Surgeon and Registrar. Honorarium 75, guineas, with board and residence. Applicants must address the Chairman of the Weekly Board. (See Advt.)

King's College London. The Chairs of *Materia Medica* and of *Comparative Anatomy*.

Owen's College, Manchester. Professorship of *Anatomy*. Emoluments from stipend and fees, guaranteed not to be less than £500 per annum. Full particulars on application to Dr. Greenwood.

Stockport Infirmary. House Surgeon. Salary, £80 per annum, with board and apartments. Address the Hon. Sec.

West Norfolk and Lynn Hospital. House Surgeon and Secretary. Salary, £80 per annum, with board, lodging, and washing. Testimonials, &c., to be sent to the Weekly Board, King's Lynn.

Kingston Union. Medical Officer for the new Radnor District. Salary, £80, with extra fees. Application to the Clerk before the 25th.

Burnley Union. Medical Officer of Health. Inclusive salary, £500 per annum. Address the Clerk to the Sanitary Authority, Burnley.

University of Durham. Professorship in *Biology*. Salary, £450, with a portion of fees. Candidates must apply to the Secretary of the College of Physical Sciences, Newcastle-on-Tyne.

Northampton Infirmary. House Surgeon. Salary, £125 per annum, with board and lodging. Applications to the Secretary.

Northampton Infirmary. Assistant House Surgeon. Salary, £80, with board and lodging. Address the Secretary.

North Staffordshire Infirmary, Hartshill. House Physician. Salary, £80, with board and lodging. Address the Secretary.

Buckingham General Infirmary, Aylesbury. Resident Surgeon. Commencing salary, £80, with board and lodging. Address Mr. G. Fell, Aylesbury.

Liverpool Royal Southern Hospital. Junior House Surgeon. Salary, 80 guineas. Application to the Treasurer, at the Hospital.

Denbighshire Infirmary. House Surgeon and Secretary. Must understand Welsh. Address the Chairman of Committee. Salary to commence at £35.

#### APPOINTMENTS.

ATKINSON, E., M.R.C.S., a Surgeon to the Leeds General Infirmary.  
CAMPELL, W., M.D., C.M., House Surgeon and Secretary to the Glamorganshire and Monmouthshire Infirmary and Dispensary.

DENTON, E. R., M.R.C.S.E., Medical Officer and Public Vaccinator for No. 2 District of the Leicester Union.

DUNCAR, A. J., M.D., L.R.C.S.Ed., a Physician to the Dundee Royal Infirmary.

EDGE, A. M., M.D., M.R.C.S.E., a District Surgeon to the Salford and Pendleton Royal Hospital and Dispensary, Manchester.

FINEGAN, Dr. J. S. F., Medical Officer to the Finglas and Glasnevin Dispensary District.

FLAMSTEAD, W. R. D., L.R.C.P.Ed., House Surgeon to the District Hospital, West Bromwich.

FLEMING, J. N., M.D., a Physician to the Newcastle-on-Tyne Dispensary.

HAWTHORN, W. T., M.R.C.S.E., Medical Officer to the Workhouse and for the Northern No. 2 District of the Wellington, Salop, Union.

HERMAN, G. E., M.R.C.S.E., House Surgeon to the London Hospital.

HOPE, Mr. J. W., House Surgeon to St. Peter's Hospital

LETTERS, P., M.B., C.M., Surgeon to the Middle Dispensary District, Dundee Royal Infirmary.

MACEWAN, D., M.B., C.M., Surgeon to the Dundee Royal Infirmary.

MACNAB, W., L.R.C.P.Ed., L.R.C.S.Ed., Certifying Factory Surgeon for Skipton, Yorkshire.

MILLER, J. W., M.D., Consulting Physician to the Dundee Royal Infirmary.

OTTLEY, W., M.B., M.R.C.S.E., Resident Surgical Officer to the General Hospital, Birmingham.

POWNE, B. L., M.R.C.S.E., Medical Officer to the Workhouse, and for No. 1 District of the Chard Union, Somersetshire.

RAHILLY, J., L.A.H.Dub., Apothecary for the Kanturk Dispensary District of the Kanturk Union.

RANGER, W. G., M.R.C.S., Assistant Dental Surgeon to St. Thomas's Hospital.

REDMOND, Gabriel O'C. F., Medical Attendant to the Royal Irish Constabulary, Cappoquin and Cross of Scart, co. Waterford; Medical Attendant Industrial School, Cappoquin.

SMITH, R. D., M.R.C.S.E., House Surgeon to the London Hospital.

TURNER, J. S., M.R.C.S.E., Medical Officer and Public Vaccinator for No. 5 District of the Mansfield Union.

WHITE, H. F., LA TOUCHÉ, L.K.Q.C.P.I., L.R.C.S.I., Medical Officer to the Workhouse of the Caxton and Arrington Union, Cambs.

## Marriages.

GILES-CAMPBELL.—On the 2nd inst., at St. James's, Paddington, Richard Giles, M.D., Oxford, to Agnes, relict of Thos. Campbell, Esq. of Annfield, Ayrshire, Scotland.

FLEMING-ENO.—On the 9th inst., at the Parish Church, Winton, J. N. Fleming, M.D., Newcastle, only son of J. Fleming, Papcastle, Cumberland, to Laura Eno, eldest daughter of J. C. Eno, Beda Lodge, co. Durham.

NEWTON-BLACK.—On the 9th inst., at St. Nicholas Church, King's Lynn, John J. Newton, of Hunstanton, Norfolk, to Agnes, eldest daughter of the late James Black, M.D., of King's Lynn.

## Deaths.

BROWN.—On the 2nd July, Geo. Brown, M.D., of York Road, Hove, Brighton, aged 60

CLARKE.—On the 20th June, Wm. H. Clarke, L.R.C.P.Ed., L.R.C.S.Ed., of Stratford-on-Avon, aged 32.

DUFFY.—On the 23rd June, Francis Duffy, M.D., of River-view, Carrickmacross, co. Monaghan.

JEFFERSON.—On the 27th June, Richard Jefferson, M.R.C.S.E., of Market-Weighton, Yorkshire, aged 74.

LYON.—On the 5th July, David Mitchell Lyon, L.R.C.P.Ed., L.F.P. Glas., of St. Helens, Lancashire.

MUDGE.—On the 27th June, Henry Mudge, M.R.C.S.Eng., of Bodmin, aged 68.

## GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

SESSION 1874.

In our last issue we gave a report of the proceedings of the Council from the commencement of the session on Thursday up to Monday afternoon. The last portion of the proceedings were only briefly reported, and it may, therefore, be well before passing to Tuesday's work to add a few particulars as to Monday.

MONDAY, JULY 13 (*continued*).

The letter from the registrar of the London University, enclosing one from the Home Office, reported to be read in our last, was in the following terms :—

University of London,  
Burlington Gardens, W.  
July 7th, 1874.

DEAR SIR,— I am directed by the Senate of the University of London to forward to you the accompanying copy of a letter from the Home Secretary, from which it will be seen that the University will now be enabled fully to co-operate in the Scheme of Conjoint Medical Examination, which has been approved by the Medical Council,

I remain, Dear Sir,  
Yours faithfully,  
(Signed) WILLIAM B. CARPENTER.

Dr. FRANCIS HAWKINS.

[COPY.]

Whitehall, 29th June, 1874.

SIR,— I have the honour to acknowledge the receipt of your letter of the 18th instant, and to inform you that I approve of the following resolution of the Senate of the University of London, viz. :—

"That henceforth no candidate, unless he have passed the Preliminary Scientific (M.B.) Examination before the final adoption of the Scheme of Conjoint Medical Examination, shall be admitted to the second M.B. examination of the University of London, until he shall have passed the final examinations of the Conjoint Board."

I have the honour to be, Sir,  
Your obedient Servant,  
(Signed) RICH. ASSHETON CROSS.  
The REGISTRAR of the University of London.

A letter from the Pharmaceutical Society of Great Britain, inclosing copy of a resolution of the Council of that body, was then read. This resolution, which expressed the readiness of the Society to co-operate in the work of the Pharmacopoeia Committee, has previously been noticed in our columns.

After this it was moved by Dr. Macnamara, seconded by Dr. A. Smith, and agreed to :

"That it is advisable that in future, proof sheets, as printed, but previous to publication, of the General Register, should be forwarded to the Branch Registrars for each division of the Kingdom for revision."

Another resolution was then submitted by Dr. Macnamara, and seconded by Dr. A. Smith to the following effect :

"That it be referred to Mr. Ouvry to instruct the Executive Committee as to the strictly legal manner in which additional titles, changes of residence, and erasures of names, should be effected on the general register."

This resolution was agreed to, and with the former will probably tend to make the register more accurate.

On motion from the Chair, the Council then resolved itself

into committee of the whole Council, when Dr. Humphry moved : "That the reports on the visitations of the medical examinations in the Queen's University, in Ireland, held June 1873, and September 1873, be forwarded to that University for consideration and remarks."

Dr. Bennett seconded the motion ; agreed to.

It was then moved by Dr. Parkes :

"That the Council desire particularly to call the attention of the Queen's University to defects noticed in the second report in the preliminary examination, and in some of the subjects of the professional examinations."

Dr. Parkes called special attention to the statement of the visitors :—"Looking to the comparatively short time allotted to the examinations, the fewness of the subjects of examination, and the meagreness of the knowledge required of candidates in the more important of them, we cannot think that the examinations are at all adequate to insure that the successful candidate shall have had even a very moderate previous education." "The clinical surgical examination struck us with its excellence so far as it went ; it appeared, however, on the whole, to be meagre. The medical clinical examination was a *bona fide* examination, but struck us still more forcibly as being insufficient. The practical midwifery examination was, within its limits, very good, but we scarcely thought it sufficiently extended or searching to justify the granting of a special midwifery diploma."

Sir Wm. Gull seconded the motion ; he was more favourably impressed with the examination of the Queen's University than with that of the College of Surgeons in Ireland. He commented on defects in spelling, and thought it wrong to allow in zoology a choice of vertebrates or invertebrates ; and the preliminary examination was very defective.

Dr. Humphrey opposed the motion. The preliminary examination was not alluded to in any other report, and it would be hard to censure the University in the absence of information as to the preliminary examinations of other bodies. The arrangements of the university were in a state of transition, and in future the examination in physics, &c., would take place at an earlier period. As to the choice allowed to candidates between vertebrate and invertebrate animals, he thought it was not injudicious ; it was better to examine the student in one branch of so wide a subject than to let him range over the whole field. He would not censure the Queen's University, and quoted the passage with which the visitors of the first examination concluded their report : "It is with much pleasure that we are able to report so satisfactorily of the medical examinations in the Queen's University. Though there are some points which, in our opinion, might be altered for the better, there are others which seem to us well worthy of imitation." The visitors of the second examination also reported : "We were very much impressed with the general excellence and thoroughness of the examinations we witnessed so far as they went." On the whole, the visitors had taken more pains to examine and criticise than was the case with regard to any other body. They were received and treated most courteously, and nothing whatever was kept from them. Every facility was given to him and his colleague ; they were even allowed to be present at the final arrangement and adjustment of the marks. The examination in anatomy was perhaps the best in the empire, and on his return to Cambridge, one of his objects was to bring the examination there into closer correspondence with that of the Queen's University.

Sir Wm. Gull again interposed to quote the following passage in the second report : "With the practical knowledge displayed in the clinical, medical, and surgical examinations we were better pleased, but, as we have pointed out, these examinations were somewhat superficial, and, had they been as searching as those in anatomy, might possibly have been attended with similarly disastrous results."

Dr. Bennett said that he and his colleagues visited the examinations of the Queen's University at examinations for the degree of M.D. ; not merely as pass examinations. The

authorities themselves admitted the defects pointed out, and were anxious to rectify them. The subject of preliminary education was touched upon because it was part of the general course for the degree of M.D. Finding the preliminary education of the majority of the candidates defective, they were led to inquire into the regulations respecting it. He agreed with Dr. Humphrey as to the wisdom of allowing a student a certain choice in regard to zoology; and intended later on to call attention to the absolute necessity of limiting the area over which some examinations extended. To take a student over the whole field of zoological science was perfectly absurd.

Dr. Fleming quoted the following statement of the visitors: "We ascertained that it was a common practice for candidates rejected at the M.D. examination of the Queen's University to present themselves at the next ensuing examination of one of the Scottish licensing bodies, and to obtain therefrom a licence to practise almost immediately after previous examiners had declared them to be unfit. He then said, many candidates came to Glasgow from Belfast, that city being as near as Dublin; and candidates from schools in the centre of England found it as easy to go to Glasgow or Edinburgh as to London. He had obtained a statistical return in regard to Irish candidates who applied for the licence of the Faculty of Physicians and Surgeons in Glasgow from 1868 to 1874, and the following was the result:—In 1868 the number of candidates educated in Ireland was 10; passed, 5; rejected, 5. In 1869 the number of candidates was 12; passed, 5; rejected, 7; number passed who had passed first examination in Queen's University, 1; number rejected who held Irish degrees, 3. In 1870, candidates, 9; passed, 3; rejected, 6; number passed who had passed first examination of Queen's University, 1; number rejected who held Irish degrees or diplomas, 2. In 1871, candidates, 12; passed, 4; rejected, 8; number passed who had passed first examination of Queen's University, 1; number rejected who held Irish degrees or diplomas, 3. In 1872, candidates, 7; passed, 2; rejected, 5; number passed who had passed first examination of Queen's University, 0; number rejected who held Irish degrees or diplomas, 4. In 1873, candidates, 5; passed, 0; rejected, 5; held Irish degrees or diplomas, 3. In 1874, candidates, 4; passed, 2; rejected, 2; number passed who had passed first examination of Queen's University, 1; number rejected who held Irish degrees or diplomas, 1. The total number of candidates during this period was 59; passed, 21; rejected, 38; number passed who had passed first examination of Queen's University, 4; number rejected who held Irish degrees or diplomas, 16. This would show whether the examinations in Glasgow were sufficiently searching. He courted any amount of inquiry into the subject, and maintained from the statistics given that the standard of examination was higher in Glasgow than in Ireland?

Dr. A. Smith asked what were the licensing bodies in Ireland whose candidates were rejected in Glasgow, and especially how many of such candidates held the licence of the College of Physicians in Ireland?

Dr. Andrew Wood said the visitors stated: "The existence of the practice here referred to, and the extent to which it is carried on, might be ascertained by requiring of all examining bodies lists of their successful and unsuccessful candidates." He did not wish to be invidious, or he could show where the candidates came from in Scotch examinations who showed lamentable ignorance in spelling. There was not a single recommendation made by the Council which the body he represented had not at once adopted.

On the motion of Sir D. Corrigan, the debate was adjourned.

#### TUESDAY, JULY 14.

The minutes of the last meeting having been read and confirmed, the Council resolved itself into a committee of the whole Council, and Sir Dominic Corrigan resumed the consideration of the report of visitations of examinations; and on the motion of Dr. Parkes, seconded by Sir William Gull, viz.:

"That the Council desire particularly to call the attention of the Queen's University to defects, noticed in the second report, in the preliminary examination, and in some of the subjects of the professional examination."

Sir Dominic Corrigan moved as an amendment:

"That all comment and criticisms of the reports of visitations be suspended until the reports of visitations of all the licensing bodies be laid before the Council; and that the resolution

of Sir W. Gull, seconded by Dr. Parkes, on July 11, 1874, in reference to the Royal College of Surgeons in Ireland, be, and is hereby, rescinded."

This debate being of special interest to many of our readers, and perhaps the one most exciting of the whole session, we give a fuller report than of some other proceedings.

In support of his amendment Sir Dominic Corrigan said he was more convinced than ever the Council had done wrong in coming to any conclusions until the reports as to all the corporations were before them. They were now in this remarkable position: Dr. Parkes and Sir William Gull, who in respect of the College of Surgeons and the Queen's University changed places like the characters in a pantomime, urged a censure; while one of the visitors, Dr. Humphrey, stated that the examinations in the subjects that were the foundation of all medical studies were so good, that he wished to adopt the same system in Cambridge. Dr. Parkes had dwelt upon the defects of the preliminary examination, but in the report the visitors merely recommended that history and geography should be removed from the list of subjects. He could scarcely read that without laughing. As to the matriculation examinations at two of the colleges being "little more than a farce," the same might be said in respect of nearly all the colleges whose preliminary examinations were recognised by the Council. Dr. Parkes finding that the College of Surgeons was severely dealt with by the resolution passed on Saturday, by way of compensation, proposed to be twice as unjust to the Queen's University. For years Dr. Parkes had shown hostility to the Queen's University. It was the youngest child of the Medical Council—the last created University, and seemed in its infancy unable to protect itself. Whilst this young Hercules was in the cradle, two serpents were sent to strangle him, but the baby proved too strong for them, and now he defied all attempts to injure him. Dr. Parkes proposed in 1870 a resolution upon which there was a discussion occupying two days. It was in these words: "That it be an instruction to the Executive Committee to communicate to the Privy Council the correspondence between the Registrar of the Queen's University in Ireland and the General Medical Council, and to urge upon the Privy Council the necessity of refusing registration to the graduates of the Queen's University until the University complies with the recommendation of the General Medical Council on the preliminary examination of medical students." Dr. Parkes withdrew that resolution, but allowed four years to pass without attempting to carry his threat into execution.

Dr. Parkes here said he had repeatedly in Sir Dominic Corrigan's hearing given his reason for not doing so, which was that the Medical Act did not authorise the interference of the Privy Council in reference to preliminary examination.

Sir Dominic Corrigan replied to this—"Then you brought forward an illegal resolution."

Dr. Parkes said he did not know it at that time.

Sir Dominic Corrigan retorted, "You ought to have known it before proposing a resolution then damaging to the reputation of the Queen's University."

Dr. Parkes: "I have explained the whole thing several times."

Sir Dominic Corrigan went on to declare that as to the censure or praise of the Council the Queen's University felt exactly as it did from the commencement. It had done its work well, and had obtained the highest distinction at the examinations of the Army Medical Board. With those results before the Council, Dr. Parkes ought not to have brought forward his resolution, which was the most unbusiness-like resolution he had ever read. It spoke of defects "in some of the subjects of the professional examinations" without specifying any. Sir Dominic then drew the attention of the Council to some passages in the report, which had been omitted by those who had criticised it: "The answers are written in books, which must be given up without mutilation, in order to prevent the candidates from communicating with one another by slips of paper. Notwithstanding these precautions, and the presence of Mr. Stoney, the Secretary, who exercised unusual vigilance, instances of communication between the candidates occasionally occurred and were observable. We mention this rather to indicate the great difficulty of conducting an examination satisfactorily than to criticise the conduct of the examination in this instance, which appeared to us to be particularly good."

Sir Dominic would like to know if that was one of the defects in the professional examination? Again—"The clinical examinations are conducted in the hospitals and union houses, the precise place in which each examination is to take place not being made known to the students till the morning of the examination." Was that a subject for censure or for praise? It was unfair in criticising a report to omit such passages. He would read another: "The examiners in anatomy and physiology, in chemistry, botany, zoology, modern languages, and experimental physics, are the professors of the three colleges, and are therefore permanent examiners. The three professors of the three colleges act together as examiners in each subject. Those in midwifery, medicine, surgery, medical jurisprudence, and materia medica (there is only one in each) are appointed by the Senate, and hold office for two years." That, surely, was a very fair court of examiners; every two years they changed the major part of the examiners in arts and in medicine. In some other universities the same examiners were continued for life, and yet, whilst reports as to those bodies which had such faults in them were not before the Council, they were asked to censure the Queen's University. "The questions are ranged under the names of the examiners who have severally set them, and the answers to the questions of each examiner are looked over, and the marks assigned by that examiner. By this means, no doubt, trouble and time are saved, and we did not observe that any evil resulted from it." Was not that a subject for praise? Great fault had been found with the practice of allowing a man to choose between the papers on vertebrate and invertebrate animals; but he thought one of those subjects was quite enough, and it was certainly a better plan than that of another university, which divided its course into civil history and natural history—the first part consisting of the history of England from the accession of George I., and the second part of vertebrate and invertebrate animals. Upon the examination in practical anatomy, the visitors said: "The examination was conducted in a remarkably thorough, searching, and efficient manner. For instance, one candidate who had dissected the axilla was examined successively on the upper part of the thigh, the digastric triangle of the neck, the outer side of the leg, the bend of the elbow and the upper arm, the posterior wall of the abdomen and thorax, and the cranial cavity, as well as upon the axilla, which he had himself dissected. He was then examined on the superior and inferior maxillary bones, the tibia, fibula, and patella." Was it fair in Dr. Parkes not to call attention to such a passage as that? "The oral examination on the bones and on the dissections were conducted by the several examiners separately, the pupils as a rule not being questioned by the professor of their own college." At several other universities a man was examined in books from which he had been carefully taught. The clinical examination in surgery was "well conducted," and in the oral examination "the questions, which were varied, were good, and generally well answered. It occupied more than the three hours allotted for the paper, and had to be continued on a subsequent occasion." That could not have been a bad examination. The reason the visitors gave for recommending that there should be two examiners in clinical surgery was very curious: "because, among other reasons, in the investigation of patients there is not unfrequently room for some difference of opinion;" so that they suggest that there should be a row at the patient's bedside. (Laughter.) "The introduction of anatomy and physiology as parts of the final examination appears to us to form a very valuable and important feature in the system of this University." That was a most important point. "A knowledge of these subjects, so essential to the successful practice and the scientific pursuit of medicine, can, as a rule, be obtained only during the period of student life. When the examination in them is confined, as is usually the case, to the primary examination, these subjects are studied only for a short period, and at a time when their practical bearings can be but insufficiently appreciated by the student. They are hence liable to be soon forgotten. This—which is felt by many teachers to be a serious evil attendant upon the system, now universally followed, of completing the anatomical and physiological education and examinations at the end of the second year of the medical curriculum—is avoided in the Queen's University by repeating the examination in these subjects at the close of the curriculum." Was that matter for censure?

Dr. Parkes here interrupted to ask if the gentleman whose

answers were printed at page 163, and who passed the examination for M.D., was examined in the modern languages, especially in English?

Sir Dominic Corrigan replied: Certainly, and proceeded to read the following passage at page 205: "But when we consider the fact that candidates are only required to attend the medical practice of a hospital containing sixty beds, of which probably thirty only are medical, for a period of two years without necessarily holding the office of clinical clerk or taking any part in the management and treatment of the patients, it would almost appear that the medical examinations were reduced in stringency and relative importance in deference to the slender clinical experience of the expected candidates." Sir Dominic declared that a student might learn much more from carefully examining cases in a hospital where there were only sixty beds than from wandering about among 200 or 300 beds, and cursorily looking at cases. The report continued: "It does not appear from the calendar that a candidate for the M.Ch. needs to have filled the office of dresser." Was that necessary? How was every student to get the office? It is impossible to make all dressers.

Dr. Parkes again interrupted to say: The report goes on to say, "or that the candidate for the midwifery diploma needs not to have conducted a single case of midwifery."

Sir Dominic Corrigan said that was not correct. He did not read it, because he did not wish to be too hard upon the visitors. Several pages of the report were occupied with arguments upon the futility of testing the merits of candidates by figures. At page 212 they said, "the number of examiners in medicine, surgery, midwifery, materia medica, and forensic medicine should be doubled." Very good, but where were the funds to come from? The Treasury who examined the accounts might possibly object. At page 213 there was the paragraph about which so much had been said—that candidates rejected by the Queen's University, as a "common practice," presented themselves to Scottish licensing bodies, and obtained the necessary qualifications from them. What proofs of that had the visitors? If they had none, they ought rather to have cut off their hands than have written such words.

Dr. Aquilla Smith seconded Sir D. Corrigan's amendment.

Dr. Parkes in reply said, the only reason for the charge of hostility which Sir Dominic Corrigan had made was, that some years ago he had brought forward a motion urging that the Privy Council should disallow the registration of Queen's University men until that University had complied with the suggestions of the Medical Council. Some years ago there was a visitation of the Queen's University, and the visitor reported that the University had not complied with the regulations of the Medical Council. A committee was appointed to consider the various reports, and that committee put this paragraph in its report: "The Committee are informed that a student may follow his professional studies for two years before passing his preliminary examination in arts. The attention of the University should be directed to the evil of this, as permitting insufficiently educated persons to enter on professional studies." He proposed that the Registrar should write to the Queen's University requesting their attention to this report, and pointing out that they were not complying with the recommendations of the Council. The Registrar wrote a second time, but to that letter there was no answer, or a doubtful one. He therefore addressed a few questions to Sir Dominic Corrigan, but he might as well have addressed them to an eel. At one time he was not in the Council, and at another time he appeared to misunderstand the questions; but he was far too sharp to misunderstand anything; he could not get an honest "yes" or "no" from him. Then he brought forward the resolution which Sir Dominic had read, but after bringing it forward he was informed that the Privy Council could not judge between the Council and the Queen's University because it concerned preliminary, not professional education. The President asked him to withdraw the resolution, and he did so. He disclaimed any hostility to the Queen's University. Some of the professors were his personal friends, and the University had done good service in Ireland. Until he read this report he was of opinion that it had done much better. He was obliged to Sir Dominic for calling attention to the resolution proposed in 1868, because the Council would see that nothing had been done in the Queen's University in compliance with the suggestions of the Council

for the last seven years. With the exception of anatomy, there was not a subject upon which something serious was not reported. Dr. Bennett said what he could to extenuate this; but did he wish the Council to take what he said yesterday or what he had written! If he wished to eat his own words he could not eat the words of his colleague, Dr. Bristowe.

The President said he did not believe there was one body recognised by the Council whose preliminary examination was a "farce."

Sir William Gull protested against its being said that any member of the Council was actuated by hostility because he felt it his duty to criticise a report. He had known Dr. Parkes for thirty years, and he was the most honourable and fair man he knew. If the Council rescinded its resolution he would move that they should go before the Privy Council with the report in their hands. (Hear, hear, from Sir D. Corrigan.) It was utterly unbecoming that personalities should pass between members of the Council.

Dr. Bennett said that this, to the best of his belief, was an honest report. Dr. Bristowe and himself were open to receive information from any quarter that presented itself, and there was not a statement in the report which was not given on credible authority. It would be a breach of confidence if they were to give up the names of those who supplied information. They did not go outside Queen's University for the information. He sympathised with the remarks of Sir William Gull, in reference to Dr. Parkes, who was on the committee on preliminary examinations, and did no more than his duty in insisting upon returns which have never yet been received from Queen's University.

Dr. Andrew Wood deprecated the tone of Sir Dominic Corrigan's remarks, but the statements of that gentleman had convinced him that the Council ought not to censure the Queen's University. He hoped, therefore, that they would not adopt the motion of Dr. Parkes. He believed they were justified in the course they had taken with regard to the College of Surgeons, especially in the matter of their refusing to give up the papers. He did not impeach the honesty of Dr. Bennett's report, nor the industry with which it had been drawn up; the industry was really excessive, for several pages were devoted to observations upon the system of giving marks, which appeared so far-fetched that they were not worth the trouble of reading. Dr. Bennett was bound, in his opinion, to give his authority for the invidious passage at page 213, relative to men rejected at the Queen's University obtaining Scotch diplomas. Dr. Fleming's statistics proved that the remark could not apply to the body he (Dr. Fleming) represented. To whom then did it apply? Dr. Bennett was bound to state what evidence there was of that, and the data on which that statement was made. A great many candidates came over from Ireland to the Scotch examinations; if they were badly prepared they were rejected, if they were well prepared they passed. His defence to the accusation was the reports of the visitors themselves. Had they said that the examinations were improperly conducted, or had they made such remarks as would imply censure? They had not, because there was no ground for it. He should be very glad if Dr. Bennett would state where he got his facts, for the amount of bad feeling that that paragraph had produced and would produce in Scotland was very great.

Dr. Bennett said Dr. Wood himself would be very much surprised if he were to hear some of the sources whence that information came.

The President thought it undesirable to continue the discussion, as the matter would come before the Council at a subsequent sitting.

Dr. Humphry said one of the first duties of the Council was to behave fairly to the various bodies with reference to whom these visitations were made. Several visitations had been made, and in each case some points were mentioned which might be amended. There was no one body on which such high encomium had been passed as that contained in the last paragraph of the report now under consideration. His impression and that of his colleague with regard to the Queen's University was that it was one of the best examinations they had ever witnessed. If the Council passed a motion of this kind, they would be passing it in opposition to the opinion of the two gentlemen sitting at that Board who made the visitation of those examinations—namely, Dr. Bennett and himself.

Sir D. Corrigan said he would be most happy to assist Sir

W. Gull in carrying out his object. Let them meet before the Privy Council and see what the result would be.

Dr. Macnamara said he was never more astonished in his life than at the tone adopted by some of the speakers. It would be more becoming their position, if, instead of making sneering remarks, full of personalities, they were calmly to discuss the questions, and to point out the defects existing in the respective bodies; but let it be done in a spirit of fair play. For his part, he should be very happy to go to the Court of Appeal, for the reputation of the Royal College of Surgeons of Ireland stood second to that of no other surgical body. They had long held the very highest position in the opinion of medical authorities and the public. If Sir D. Corrigan stated that the preliminary examinations of some colleges were farces, he would go farther, and say every examination that the Council accepted must be a farce, because all the subjects that were included in the curriculum laid down by the Council were absolutely included in the curriculum of the College of Surgeons. He had most carefully read the report of the visitors at the Queen's University. For two years he had himself filled the office of examiner in the Queen's University, and could testify to the manner in which its pupils were most skilfully examined. The resolution of Dr. Parkes was stronger than that which had been passed with reference to the College of Surgeons. The Council must bear in mind that the rule in Ireland was the adoption of the double qualification, and for practitioners not to rest satisfied with the single qualification at the College of Surgeons, valuable though it might be. Therefore the examiners at the Council of Surgeons might possibly only ask a few superficial questions with regard to matters belonging to the other qualifications, just so as to provide that the candidate should know something about them, in case by accident he went out to practise with a single qualification. He should urge for no man to be allowed to practise without the double qualification, and in that case the College of Surgeons would refrain from putting any questions at all on the subject of disease, but would leave it in the hands of the College of Physicians. Sir W. Gull adopted a rule well known in Ireland, that when a person had a bad case he must abuse the opposite counsel. There was a species of blindness which was very remarkable, in which people could not see some things in daylight, whilst they could see other things in the night-time. He invited Professor Sharpey to turn his attention to this remarkable phase of blindness, as exhibited by Sir W. Gull.

The President here reminded Mr. Macnamara of the caution he had himself given with regard to personalities.

Mr. Macnamara said he felt he must give it to Sir W. Gull. If Sir W. Gull had had an idea of fair play he would never have suppressed this sentence: "In conclusion, we may remark that the good points of this examination are sufficiently obvious. It combines, in a very appropriate and advantageous manner, a written, an oral, a clinical, and a practical examination; and if efficiently conducted—"

Sir Wm. Gull.—"If."

Mr. Macnamara.—"If" is introduced into every one of the reports. "If efficiently conducted, it is difficult to conceive that any candidate could pass who had not acquired a thorough knowledge of the foundation of personal attainments. Its defects, on the other hand, as at present conducted, are no less patent; and we have the less hesitation in referring to them since we have reason for believing that they are recognised by several members of the Council, and are likely to be in part removed by changes about to be adopted." He hoped the Council would refuse to pass the resolution.

Dr. Quain could not give a silent vote on this question. He did not regard Dr. Parkes' motion as a vote of censure, but as they had not directed the special attention of the other bodies to the reports, he could not support a motion for directing the special attention of the Queen's University to its report. With regard to the College of Surgeons in Ireland, the Council could not have passed over the practice of destroying the examination papers without some special remark. There was nothing, however, in the Queen's University that called for any special remark on the part of the Council.

Dr. Acland said he agreed with Dr. Andrew Wood that it would be most unsatisfactory to vote for either amendment or motion. The terms of accusation in the report were no stronger than the terms of admiration. It was a curiously balanced document. He regretted that the Council should discuss such small questions. The moment the Council descended from its great position to interfere in details with the

great university bodies, its moral influence was gone. The late Professor Syme remarked that the influence of the Council was by leading the bodies, and not attempting to drive them. The driving power of the Council was a representation to the Privy Council. If it was thought right that they should go there, why then it would relieve them of the difficulty, and the point could be fully argued, but they must not go there except upon full evidence. He should be sorry to see one body taking upon itself to condemn another body, especially when Professor Humphrey had said that, in the judgment of himself and colleague, he did not consider the Council would be justified in sending a request which would amount to a vote of censure.

The amendment moved by Sir D. Corrigan and seconded by Dr. Smith, was then put to the Council, and rejected by a majority of 13 to 4.

The motion was then put to the vote, and was also negatived. On motion from the Chair, the Council resumed.

Dr. Storrar moved "That the resolutions of the Council in committee be adopted by the Council."

Mr. Quain seconded the motion, it was agreed to.

SIR D. CORRIGAN'S PROPOSED BILL TO AMEND THE MEDICAL ACT OF 1858, 21 and 22 vict., cap. 90, was taken as read.

Whereas it appears expedient to amend the Medical Act, August 2nd, 1858, 21 and 22 vic., c. 90 :

1. That from and after the

Clause XXXVI. be and is amended as follows :—That from and after the passing of this Act no person, unless previously registered, shall be entitled to hold any appointment as a physician or surgeon, or other medical officer in charge of sick or wounded either in the military or naval service, or in emigrant or other vessels, or in any hospital, infirmary, dispensary, or lying-in hospital, not supported wholly by voluntary subscriptions, or in any lunatic asylum, gaol, penitentiary, house of correction, house of industry, parochial or union workhouse, or poor house, parish union, or other public establishment, body, or institution; or to any friendly or other society for affording mutual relief in sickness, infirmity, or old age; or, as a medical officer of health, unless he be registered under this Act, and unless, in addition to his being duly registered, he shall also be examined and declared competent for such appointment by an examining board as hereinafter provided, and entitled to append to his name on the registry, the letters C.M.B., signifying Civil Medical Board.

2. That within the period of three months from and after the passing of this Act, it shall be the duty of the General Medical Council to appoint a Civil Medical Board, consisting of five examiners from England, five from Ireland, and five from Scotland, whose duty it will be to examine all candidates presenting themselves, who shall have passed the double examination in medicine and surgery and obtained their degrees or licenses to practice medicine and surgery from bodies legally entitled to grant such degrees or licenses, and have been duly registered as such, and that on passing such examination they shall be entitled to append to their names C.M.B. and shall be eligible to hold public appointments as provided for under Clause XI. of the amended Act.

3. That the respective local registrars for England, Ireland, and Scotland shall be the registrars for the Examining Board, and shall keep the registries and examination lists in such form as laid down by the General Medical Council, and that for such additional duties they shall be paid such salary as the General Medical Council shall allow, with the approval of the Commissioners of Her Majesty's Treasury.

4. That the Board of Examiners, as so appointed, shall be an Examining Board only, without any power to inquire into or lay down courses of education or of study.

5. That the fee for examination and certificate from the Examining Board shall not exceed five pounds, and that in case the amount so received for such examination be not sufficient to meet the expenses of the Examining Board, it shall, and may be lawful for the Lords Commissioners of Her Majesty's Treasury to award such sums as may be requisite to pay the salaries of the Boards of Examiners and their clerks.

6. That the examiners shall be appointed for three years, but not for a longer period, and shall not be eligible for re-election until after an interval of three years, and that members of the General Medical Council shall not be eligible to be appointed as Examiners.

7. That this Act shall be construed as one with the Medical Act of August 2nd, 1858, entitled "The Medical Act of 1858."

WEDNESDAY, JULY 15TH.

The programme of this day was a very full one for all that had been set down for Tuesday, after Sir D. Corrigan's Bill had been postponed, and the consideration of that Bill had itself been adjourned, and stood as the first order of the day for this afternoon.

Then a series of important notices of motion, and a lengthy report of the King and Queen's College of Physicians in Ireland stood for consideration, having been already postponed.

The first business transacted was the discussion of Sir D. Corrigan's bill. Sir Dominic supported his proposals with his usual eloquence, and he was seconded by Dr. A. Smith.

When the motion was put to the vote it was negatived. The only members who voted for it were the mover and seconder. The president, Dr. Macnamara, and Sir W. Gull, did not vote. There were, therefore, only 2 for, and 19 against.

Dr. Humphry moved, and Dr. Parkes seconded :

"That in the case of the certificates presented before admission to the examinations of the several licensing bodies, each should include a statement from the teacher or teachers that the candidate had satisfactorily attended examinations, from time to time, held on the subject of study to which the certificate relates."

This resolution was adopted.

Dr. Andrew Wood moved, and Dr. Begbie seconded :

"That it is desirable that, in the examinations on several of the subjects of the curriculum—such, for example, as botany, zoology, chemistry, and materia medica—the area of examination should be limited and defined."

This was agreed to.

Dr. Humphry moved, and Sir Wm. Gull seconded :

"That it is important that two examiners, or an examiner and assessor should be present at every clinical as well as oral examination."

Each of these resolutions gave rise to a good deal of discussion, though they were all ultimately agreed to. By this time, however, 6 o'clock had arrived, and further business was deferred until the next day.

THURSDAY, JULY 16TH.

The minutes of the last meeting having been read and confirmed,

Dr. Acland moved :

"That the Report of the Committee on the Adulteration of Food Act be received and entered on the minutes."

Mr. Quain seconded this, and it was agreed to.

It was then moved by Dr. Acland, seconded by Dr. Quain, and agreed to :

"That the Report of the Committee on the Adulteration of Food Act be considered paragraph by paragraph."

After this had been done, which occupied a considerable time, although the only change effected was reversing the first and second paragraphs, Dr. Acland moved, and Dr. Andrew Wood seconded :

"That the report, as now amended, be adopted."

This was agreed to, and the Report now stands as follows :

#### REPORT OF THE COMMITTEE ON THE ADULTERATION OF FOOD ACT, IN CONNECTION WITH QUALIFICATIONS IN STATE MEDICINE AND PUBLIC HEALTH

The Committee appointed by the General Medical Council on July 9th to consider the Report from the Select Committee of the House of Commons on the Adulteration of Food Act, 1872, in its bearings on the qualifications in "state medicine" or in "public health," instituted by any of the bodies in schedule A to the Medical Act, having duly considered the said report, have adopted the following resolutions :—

1. That no one should be eligible for the office of public analyst unless he be possessed of a certificate of competency in analytical chemistry, in the use of the microscope, and such other subjects as the Medical Council shall from time to time determine, granted by an examining board, or boards, or, as hereinafter suggested, a qualification as an officer of public health, which shall include these subjects. 2. That the office of public analyst may be held separately, or in conjunction with that of an officer of health. 3. That it is desirable that the granting the qualifications for the purpose under consideration should not be confined to any single examining board, but that one or more examining

bodies for that purpose should be established in England, in Scotland, and in Ireland. 4. That the Medical Council should have authority to define the course of instruction and the examination required for the said purposes, and to publish a list of the bodies which comply with the conditions laid down. 5. That it is desirable that it should be made lawful that the qualifications of public analyst and of officer of health should be entered on the medical register as additional qualifications when the holder is already a registered medical practitioner. 6. That a deputation from the Medical Council should be appointed to obtain an interview with the President of the Local Government Board for the purpose of conferring on the subject of the above resolutions.

—HENRY W. ACLAND, Chairman.

Dr. Humphry then proposed the following motion standing in his name.

"That in no case should the examination of a candidate by any of the licensing bodies in any subject be conducted wholly, or in great part, by the lecturer or teacher in that subject in the school in which the candidate has been educated."

Dr. Storrar seconded the motion, and it was adopted.

Dr. Humphry next moved :

"That it is desirable that observation with the microscope should form part of the examinations of candidates for a licence."

Dr. Storrar also seconded this resolution, which was carried.

The next resolution was moved by Dr. Storrar and seconded by Dr. Stokes :

"That in the opinion of the Council all examinations should, as far as possible, be objective, and conducted by persons who are experts in the subjects of the examination assigned to them ; and that in all examinations, excepting those for degrees and fellowships, the questions put should be chiefly such as have a bearing on practice."

This motion was negatived.

Dr. Andrew Wood then moved :

"That the visitations of examinations be continued, and that the Executive Committee be directed to select visitors."

Dr. Macnamara seconded this resolution, which was also carried. The Council then adjourned to the next day.

#### FRIDAY, JULY 17TH.

At one o'clock to-day the Committee of Finance assembled, as had been previously arranged, and at five minutes after two the members of the General Council took their places, with the exception of Sir William Gull, who did not put in an appearance. The minutes of yesterday having been read, discussed, amended, and agreed to, the President rose and moved that the minutes, as now amended, be confirmed. He then went on to state the nature of the interview between himself, some members of the Council, and the Local Government Board (as resolved upon previously). He explained the satisfactory results likely to follow that interview, and concluded by stating, that he hoped if he had not fully explained to the General Council all that had happened during the interview with the Local Government Board, other members of the Council that accompanied him would correct or remind him of any omission.

According to the routine for the day's proceedings, Dr. Parkes now rose and said, that in asking the question that he had given notice of he excluded Scotland ; at the same time, he hoped that his Scotch friends would enlighten him on the subject of his inquiry in so far as they were concerned. The question was—

"To ask the President if he can inform the Council whether the schemes for conjoint examinations in England and Ireland, which have been sanctioned by the Council, are being carried into effect."

Sir Dominic Corrigan invited the attention of the Council to a phrase in the "question" asked by Dr. Parkes. So far as he knew, no scheme for a conjoint examination by the English colleges had ever been agreed to by the Council. The scheme for Ireland certainly had not been sanctioned, and he was anxious to know the exact grounds on which Dr. Parkes put forward the statement he had made.

The President read extracts from various reports, commencing March, 1872, and of subsequent dates, in which suggestions for and observations on a contemplated conjoint scheme for England had been made.

Dr. Parkes considered Sir Dominic Corrigan's objections to the question he had asked, captious.

Sir Dominic Corrigan felt that the observations made by the President justified the remarks he had made. As he had said, no scheme had been sanctioned. Sir Dominic read from the published reports extracts illustrating the position he took, and denied that a conjoint scheme for Ireland had been adopted.

The President announced that the Bill intended to enable the Apothecaries' Company to take part in the conjoint scheme for medical examination had just received the Royal assent. He sincerely wished that all difficulties would be removed from the licensing bodies in order to perfect the conjoint examination scheme, and again quoted extracts from reports on the subject.

In the discussion that followed, Drs. Beunett, Wood, Storrar, and Mr. Bradford took part.

It being now agreed that the election of the Executive Committee should proceed, Mr. Quain rose and stated that during the last sitting some medical practitioners in the country wrote to know if representatives from them should not get seats at the Board. He wished that members, when they went to ballot, would bear in mind whether the Council could not become more of a representative body.

The President said there were six members required to form the Executive Committee, four of whom should be English, and one each for Ireland and Scotland.

The election then proceeded, and the result of the ballot being called over,

Dr. Wood remarked that on the reading over the first ballot list Ireland was not represented.

Sir Dominic Corrigan considered if the lists excluded from them Irish names, and that the Committee had not on it an Irish representative, a breach of faith to Ireland would be the result.

On analysing the ballot lists, the following members of the Council had been chosen to act on the Executive Committee, exclusive of the President: Dr. Bennett, Dr. Acland, Dr. Andrew Wood, Dr. Aquilla Smith, Dr. Sharpey, and Dr. Quain.

It was proposed by Dr. Apjohn :

1. "That the Medical Council are of opinion that the number of *paper* questions in chemistry should not be less than ten, and that there should be no limit as to the proportion of those which the student is required to answer.

2. "That one-half of said questions should relate to general chemistry, and that the remainder should be taken from such departments of chemical science as have a bearing on physiology, pathology, and medical jurisprudence.

3. "That the *vivâ voce* examination should be such as would test the ability of the student to solve a few of the most simple problems in qualitative analysis, and apply to their respective uses the volumetric solutions of the *British Pharmacopœia*."

Dr. Apjohn contended that it would be quite impossible for a couple of questions to be a sufficient test in chemistry. In the interest of the student he stated this much in respect to the first part of his motion. Regarding the second portion of it, it must be obvious that the student should be required to have a knowledge of physiology, pathology, and medical jurisprudence. The third portion of the motion he maintained should be such as to test the ability of the student, to solve problems in qualitative analysis, and voluminous solutions of the *British Pharmacopœia*.

Dr. Parkes seconded the resolution, and in doing so bore testimony to the high character all acknowledged to Dr. Apjohn in chemical matters. For his part, he did not mean to enter into details—such was not advisable. He considered that the student should have placed before him a great many simple and practical questions. He agreed with Drs. Wood and Storrar that the examinations should be to test the student fully and practically.

Dr. Sharpey did not consider the number of questions should be at all fixed upon before examination.

Dr. Aquilla Smith believed ten questions a fair average for both examiner and candidate.

Professor Turner could not agree to the resolution. He agreed with Dr. Parkes that details should not be entered into, and chemistry should be deferred until physiology and pathology had been examined in by candidates.

Sir Dominic Corrigan thought that it would be quite out of their power to pass between the candidate and the examiner.

On a division being called for, the motion became lost by two votes.

Proposed by Dr. Smith: "Consideration of tables showing results of examination," as follows:—

Dr. A. Smith moved that the report be entered on the minutes; this was seconded by Dr. Macnamara.

# TABLE SHOWING RESULTS OF PROFESSIONAL EXAMINATIONS FOR DEGREES, DIPLOMAS, AND LICENCES GRANTED IN 1873 BY THE BODIES IN SCHEDULE A OF THE MEDICAL ACT.

Chemistry.....	68	7	59
Botany.....	69	4	65
Materia Medica.....	64	18	46
Physics.....	47	..	47

§§ Of these, 11 passed at a subsequent Examination within the year.

||| Of these, 7 passed at a subsequent Examination within the year.

¶¶ Of these passed at a subsequent Examination within the year.

The letter and report received by the Council from the King and Queen's College of Physicians in Ireland, were next considered.

Dr. Storrar objected loading the proceedings of the Council with such reports. They should have a printing office, if this were allowed.

Dr. Apjohn considered the report should be entered.

Dr. Leet did not think it fair to enter on the minutes the report. The original report has not been before the Council, and as a representative of the Apothecaries Hall of Ireland, he objected placing on the minutes the report of one body only.

Dr. Fleming proposed that the report be published as an appendix.

Sir D. Corrigan thought the report a private matter; the University of Dublin, King and Queen's College of Physicians in Ireland, Royal College of Surgeons and Apothecaries' Hall agreed to a report, and the College of Physicians simply took on themselves to publish it.

Professor Turner proposed the following amendment in reference to the matter. It was seconded by Dr. Storrar and passed.

"That the Council acknowledge receipt of the letter and report from the King and Queen's College of Physicians in Ireland, and thank the College for their courtesy in forwarding them."

The following is the correspondence and report referred to:—

King and Queen's College of Physicians, Ireland,  
7th July, 1874.

DEAR SIR,—By this post I send you 25 copies of the report of the College upon the report of the Committee of Reference, which this College adopted at a special meeting held yesterday.

I am, dear Sir,

Yours faithfully,

J. MAGEE FINNY, Registrar.

FRANCIS HAWKINS, Esq., M.D.,  
Registrar, General Medical Council.

Report (May 1874) of the King and Queen's College of Physicians in Ireland of the Report Committee of Reference, respecting the education and examination of candidates desirous of obtaining licence to practise medicine and surgery through the Conjoint Examination in Ireland, instituted under Section XIX of the Medical Act (1858), by the following authorities:—The University of Dublin, the King and Queen's College of Physicians in Ireland, the Royal College of Surgeons, Ireland, the Apothecaries' Hall of Ireland.

#### TIMES AND PLACES FOR HOLDING EXAMINATIONS.

1. That the Preliminary Examination be held at Trinity College, Dublin, twice annually, during the months immediately preceding the Winter and Summer Sessions.

2. That the first professional examinations be held in the months of April, July, and December respectively, and that the final professional examinations be held one in each month during the year, except in the summer vacation, which shall include the months of August and September; but, that in case of emergency it shall be in the power of the Committee of Reference to fix an examination in the months of August or September.

3. That the first professional examination (with the exception of practical pharmacy) be conducted alternately at Trinity College and the Royal College of Surgeons.

4. That the final examination (with the exception of operative surgery), be conducted, alternately, at the King and Queen's College of Physicians and the Royal College of Surgeons; and that the examination in operative surgery be conducted at the Royal College of Surgeons.

#### MODE OF CONDUCTING EXAMINATIONS.

5. That each candidate shall be examined by two examiners in each of the subjects for the first professional or final examinations (with the exception of practical pharmacy), in which he shall be subjected to one examiner only.

6. That in the case of a smaller number of examiners than those enumerated in the schedule of the scheme being employed in the examination of candidates in any subject, such examiners shall be selected by rotation.

#### FIRST PROFESSIONAL EXAMINATION.

7. The first professional examination shall be conducted by papers and orally, in each of the subjects; with the exception of practical pharmacy, which shall not include any written examination.

8. That the first day of the first professional examination shall be devoted to the answering of the printed questions, and that the candidate shall be allowed from 10 o'clock a.m., to 1 o'clock p.m., to answer questions on anatomy and physiology;

and from 3 o'clock p.m., to 6 o'clock p.m., questions on botany, materia medica, and chemistry; one hour and a half being devoted to chemistry, and one hour and a half to botany and materia medica.

9. That the oral and practical part of the first professional examination shall commence on the day succeeding the written examination. The attendance of each candidate at this part of the examination shall be for not more than one hour and a half in chemistry and pharmaceutical chemistry, and for not more than one hour in each of the other subjects.

#### FINAL EXAMINATION.

10. The final professional examination shall be divided into three parts, and be conducted in the following order:—

1. Clinical medicine, clinical surgery, and operative surgery; 2. Examination by printed questions on all the subjects; 3. *Viva voce* examination on all the subjects.

11. Each candidate shall be required to attend, at a time, and at a hospital specified, for the purpose of clinical examination, in cases in medicine and surgery, for one hour in medicine, and one in surgery.

12. Each candidate shall be examined on surgical instruments and appliances, and shall be tested by operations on the dead subject.

13. Each candidate shall be allowed one hour and a half for answering the printed questions on each subject.

14. The attendance of each candidate at the oral part of the examination shall be for not more than one hour in any one subject.

#### COURT OF EXAMINERS AND METHODS OF JUDGING CANDIDATES ANSWERING.

15. That the Court of Examiners at both the previous and final examinations shall consist of the chairman and the examiners who have taken part in the examination.

16. That the Chairman of the Court of Examiners shall be a member of the Committee of Reference, appointed for each examination by the committee from the representatives of the various medical authorities co-operating in the scheme.

17. That the question of the passing or rejecting of a candidate, at either of the professional examinations, shall be decided by the votes of the members of the Court of Examiners who have taken part in his examination, upon a review of the candidate's answering in each and all of the subjects.

18. That in the case of a candidate, who has shown himself deficient in one only of the subjects of the previous professional examination, it shall be in the power of the Court, if they are unanimous in their opinion, to remit him to a subsequent examination in that subject alone.

19. Each examiner shall mark each candidate on a scale from 0 to 10; 0 signifying no answering, and 10 signifying complete answering.

20. The Committee of Reference shall, as soon as convenient after each examination, report to the co-operating authorities the results of the examination, and such other matters pertaining thereto as the committee may deem it advisable to bring under the notice of the authorities.

#### FEES—PAYMENT OF EXAMINERS AND SECRETARY.

21. That the fees to be charged shall be as follows:—For the preliminary examination in arts, £2 2s.; For the previous professional examination, £15 15s.; For the final professional examination, £15 15s.

22. That no portion of the fee for the preliminary examination shall be returned a rejected candidate, but that he shall be permitted to present himself for re-examination on payment of a further fee of one guinea. 23. That the admission fee, with the exception of five guineas, deducted to meet the expense of the examination, shall be returned to any candidate who may be rejected at either of the professional examinations; and an extra fee of two guineas shall be charged each candidate for his re-examination on any subject upon which he may have been remitted. 24. That each examiner in chemistry, in anatomy and physiology, in medicine, and in surgery, shall receive fifteen shillings, and each examiner in the other subjects seven shillings and sixpence, for each candidate examined by him. 25. That a secretary be appointed to transact the business arising in connection with the Conjoint Scheme, under the directions of the Committee of Reference and that he be paid a salary of £ a year.

#### FINANCE.

26. All moneys payable on account of examinations held under "the Conjoint Examining Scheme for Ireland" shall

be lodged in the Bank of Ireland to the credit of the "committee of reference of the Conjoint Examining Scheme."

27. That cheques shall be drawn only in pursuance of a vote of the committee of reference. That such cheques must be signed by the chairman of the meeting at which such payment is ordered, and by one representative of the College of Physicians, and one representative of the College of Surgeons. 28. The committee of reference shall twice, annually, present to the co-operating medical authorities a statement of their accounts, made up to the 30th of September and 31st March respectively, and duly audited by two auditors (one appointed by the College of Physicians and one by the College of Surgeons). That the committee of reference shall, having discharged all liabilities, pay over to the College of Physicians and Royal College of Surgeons the surplus, in the proportions provided in Sect. 15 of the Scheme.

#### CURRICULUM OF STUDY

*To be required of Candidates desirous of obtaining Licence to Practise Medicine and Surgery through the Conjoint Examination in Ireland.*

Candidates shall be required to produce documentary evidence—1. Of having been engaged in the study of medicine for four years. 2. Of having passed the Preliminary Examination in manner defined in Sect. V. of the Conjoint Examining Scheme, or an equivalent examination, approved by the committee of reference. 3. Of having studied at any recognised medical school or schools, the following subjects for the periods specified, viz.:—Practical Anatomy with demonstrations and dissections: for two winter sessions. Anatomy and Physiology: for two winter sessions; or Anatomy and Physiology: for one session: and Institutes of Medicine: for one session. Botany: for three months. Chemistry: for one winter session. Practical Chemistry, with Instruction in the Laboratory: for three months. Materia Medica: for three months. Practical Pharmacy: for three months. Principles and Practice of Medicine: for one winter session. A Course of Practical Medicine, to consist of not less than twenty meetings of the class. Principles and Practice of Surgery: for one winter session. Operative Surgery: for three months. Midwifery: six months' course of lectures. Medical Jurisprudence: for three months. Public Health: for three months. 4. Of having attended a recognised clinical hospital for twenty-seven months, during which, regular courses of clinical instruction are delivered. 5. Of having attended practical midwifery at a recognised lying-in hospital, or maternity, for six months, and conducted ten cases of labour.

*Preliminary Examination.*—Candidates for the preliminary examination shall produce evidence—Of having lodged in the Bank of Ireland to the credit of the committee of reference the sum of two guineas.

*First Professional Examination.*—Candidates for the first professional examination shall produce evidence—1. Of having passed the preliminary examination. 2. Of having lodged in the Bank of Ireland to the credit of the committee of reference the sum of fifteen guineas. 3. Of having been engaged in the study of medicine for two years. 4. Of having attended a recognised clinical hospital for nine months. 5. Of having been engaged for two winter sessions in the study of practical anatomy, with demonstrations and dissections, and of physiology. 6. Of having attended one course of lectures on each of the following subjects:—Anatomy and physiology, botany, chemistry, and materia medica. 7. Of having been engaged for three months in the study of practical chemistry, and three months of practical pharmacy.

*Final Professional Examination.*—Candidates for the final professional examination under the Conjoint Examining Scheme, shall produce evidence, in addition to that required previous to admission to the first professional examination—1. Of having passed the first professional examination under the Conjoint Scheme, or having fulfilled the conditions provided in Section 12 of the Conjoint Examining Scheme. 2. Of having lodged in the Bank of Ireland, to the credit of the committee of reference, the sum of fifteen guineas, except in the case of graduates in arts, when it shall be five guineas, as provided in Sect. 16 of the scheme. 3. Of having been engaged in the study of medicine for two years. 4. Of having attended a recognised clinical hospital for

eighteen months. 5. Of having been engaged for one winter session in the study of practical anatomy, with demonstrations and dissections. 6. Of having attended one course of lectures on each of the following subjects:—Anatomy and physiology or the institutes of medicine, practice of medicine, practical medicine, surgery, operative surgery, midwifery, medical jurisprudence, and public health. 7. Of having attended for a period of six months a recognised lying-in hospital or maternity, where clinical instruction is given, and conducted thirty cases of labour.

Moved by Dr. Fleming, seconded by Dr. Apjohn.

"That it be an instruction to the registrars before they enter the name of any applicant for registration on the *Medical Register*, to ascertain by reference to the register of *Medical Students*, whether the period of time required by the Medical Council to be devoted to professional study, has elapsed between the date of the applicant's registration as a student of medicine and the date of his license. And further, that the registrar of each branch council shall report to his Council any case where this has been departed from, and take instructions from them as to any future proceeding.

Dr. Fleming considered the time had come when it became necessary to entertain this matter, all old students, not coming under the four years of study test, have been by this time disposed of; the motion proposed he believed to be a good and practical one.

Sir D. Corrigan considered it quite out of the province of the Council to pass the resolution, and according to the Act of Parliament, it could not be entertained. Having read the section of the Act bearing on the point, he believed the Council would be open to actions if the resolution were passed and acted on.

Dr. Storrar sympathised with Dr. Fleming in the matter, yet he felt he should advise Dr. Fleming to withdraw this resolution.

The President quite agreed with Dr. Fleming, but he considered the resolution was open to the objections stated by Sir D. Corrigan.

On a vote being taken the motion was lost.

The following question by Dr. A. Smith was then submitted to the Council:

"Dr. A. Smith will ask the representative of the University of Aberdeen if any proceedings have been taken by that University respecting an M.D. of Aberdeen, who was sentenced to four months' imprisonment at Inverness Circuit Court for fabricating certificates of vaccination."

Professor Turner in reply, stated as name and date were omitted, all he could do was to bring the case alluded to before the authority of his College for investigation.

Mr. Bradford moved and Dr. Storrar seconded:

"That certain correspondence between the Society of Apothecaries and the Lord President of the Council be now read, and placed on the minutes

"Also, that a letter from the Master of the Society of Apothecaries, dated 5th June, 1874, addressed to the President of the General Medical Council, be also read."

Mr. Bradford gave a detailed account of the correspondence between the Lord President and apothecaries, as relating to the bill that has just received the royal assent, and ended by proposing, and Dr. Storrar seconded:

"That the letters be entered on the minutes, the objection to their publication having ceased to exist."—Carried *nem. con.* (This correspondence shall appear in our next issue.)

This "question," by Dr. Andrew Wood, was then put to the Council:

"Dr. Andrew Wood to ask the representative of the Royal College of Surgeons of England if the name of Matthew Bass Smith, which was removed by the Medical Council from the *Medical Register* at its last session, is still on the roll of members of the Royal College of Surgeons of England."

Mr. Quain explained that the law adviser to the College gave it as his opinion that they had not the power to expunge the name from the College rolls. Last year the Council took up the matter, and the law adviser of the Council gave it as his opinion they had not the power to act as they contemplated. Subsequently Mr. Quain applied to the College to see if a bye-law to meet similar cases could not be passed, and received a reply that the College was progressing in framing a law to that effect.

Dr. Macnamara moved:

"That, with a view to its being either amended, or to being recommended to the Executive Committee to act in accordance with its provisions for the future, he will draw the

attention of the Council to standing order XIV., section 2 ;"—viz.:

"That a form for appointing members be prepared, and sent by the registrar to the secretary of State (Lord President of the Privy Council ?), and to each body having power to appoint, two months before the expiration of the term of the existing appointment, so that the new appointment may be made to take effect from the day on which the old appointment shall expire.

Dr. Macnamara explained the object of his motion was to prevent a hitch in the working of the Council. He gave extracts from the Act, and from the proceedings of the Irish College of Surgeons. He considered if the standing orders relating to these matters were wrong they should be revised. Great delay and inconvenience arose from this matter on the resignation of Mr. Hargrave, and his subsequent election to the office of councillor, and to obviate a recurrence of it he invited the Council to the serious consideration of his motions.

It being six o'clock the Council adjourned until to-morrow at noon.

#### SATURDAY, JULY 18TH.

At twelve o'clock to-day the Council assembled; the previous proceedings having been read and confirmed, the President proposed their insertion on the minutes, which was agreed to.

Dr. Apjohn then moved

"That the President be requested to ask Mr. Macnamara, for the information of the Medical Council, whether the Royal College of Surgeons in Ireland has or has not withdrawn from the scheme of conjoint examination adopted by the King and Queen's College of Physicians (June 28, 1872), and agreed to by the University of Dublin, the Royal College of Surgeons in Ireland, and the Apothecaries' Hall of Ireland; and sanctioned by the General Medical Council (March 31, 1873)." And having done so proceeded to say he held no hostility to the Royal College of Surgeons, quite the contrary. He then read from the *MEDICAL PRESS AND CIRCULAR* of the 19th March extracts from the report of meetings of the Royal College of Surgeons bearing on his motion. He did not consider it necessary to go far into the subject, as he left the matter in the hands of the College's most indefatigable representative, Dr. Macnamara.

The President having put the question:

Replying to the motion of Dr. Apjohn, Mr. Macnamara commenced by saying that in the first place he considered it necessary for him to make a few observations as to the organization of the Royal College of Surgeons of Ireland, and the mode by which its executive are elected. The fellows of the College annually elect the members of Council, and the twenty-one members of Council have the entire charge of the affairs of the College during the term of office, which is for twelve months. Regarding the motion of Dr. Apjohn, there seems a difficulty in reconciling the Fellows as to the mode by which the conjoint scheme should be carried out. During the month of May in each year the annual meeting of the Fellows of the College takes place, and in the subsequent month, June, the Council is elected, but long prior to that time the annual report of the College is issued and in the hands of the Fellows. The conjoint scheme is received by some unfavourably, and others are hostile to it; others are unfavourable to the proposed mode by which it is to be applied. Dr. Wharton and himself (Mr. Macnamara) were appointed by the Council to report on the applicability of the scheme to the Irish College of Surgeons, and they did so. A meeting of the Fellows was held, the subject was discussed, and they decided not so much against the scheme, but against the mode by which the scheme was to be worked out. At a subsequent meeting fourteen out of seventeen members of the Council voted in favour of the scheme, and at the annual election which followed a majority of those elected to serve as councillors were upholders of the scheme. Nothing could have spoken more "trumpet-tongued" than this fact in favour of the object aimed at; and to show with what importance the proceedings were regarded nearly 200 Fellows voted—more than ever before—even the year of what was called the "big fight" there voted only about 170. Mr. Macnamara concluded his telling and incisive remarks by thanking Professor Apjohn for having given him the opportunity of placing his College, in its relation with the proposed conjoint scheme of examination, in its true light before the Council.

Then Dr. Apjohn moved, and Dr. Parkes seconded the following resolution:

"That the Council thank Mr. Macnamara for his reply to the inquiry of the President, and are glad to find there is a

fair prospect that the Royal College of Surgeons in Ireland will eventually give its influential co-operation in carrying out the Irish scheme of conjoint examination, which has been sanctioned by the Medical Council."

Moved by Dr. Macnamara; seconded by Dr. Leet:

"That, in the opinion of this Council, all examinations on anatomy should, so far as practicable, include the performance by each candidate of actual dissections; and, that all those on surgery should include the performance by each candidate of two or more operations on the dead subject."

In submitting this motion, Dr. Macnamara wished to say that in the University of Dublin, the College of Surgeons, and Queen's University, for some time past the proposition now made had been adopted with marked effects. He agreed with Mr. Quain as to the earlier education of students intended for the medical profession, and it would be for their relatives to consider whether they should not adopt a profession which requires so large an amount of study. By the adoption of his proposal the use of the scalpel and a practical knowledge would be insisted on. He could not understand how certificates were given by gentlemen who had not tested the work of candidates.

Dr. Thomson considered the proposal of Mr. Macnamara included in proceedings anteriorly before the Council, and quite unnecessary to reopen. The Council did consider and agree that operative surgery was quite essential.

Dr. Wood said the Council having expressed their opinion, no strict or stringent rule in the matter should be laid down at present.

Dr. Fleming agreed with Dr. Wood that the resolution was unnecessary, as in all licensing bodies practical anatomy was required.

Mr. Quain believed certificates, such as Mr. Macnamara stated, should not be given. He did not consider it expedient to lay down rules. Ordinary practitioners might be, in some cases, operative surgeons—they need not be so—yet still perform the duties of their stations effectively.

Mr. Macnamara felt greatly pained that his proposal received opposition. He did not consider this would be the case, especially by such an eminent surgeon as Mr. Quain. He, nevertheless, believed operations on the dead subject was a great improvement. He believed his motion of so general a character as to merit the sanction of such an important body as the General Medical Council.

[As the opinion of the Council had not been sufficiently matured on the matter, at the suggestion of Dr. Allen Thomson the motion was withdrawn.]

The Report of the Pharmacopœia Committee as follows was now read by the Secretary:—

"The Pharmacopœia Committee beg to report that the resolutions adopted by the Council at its last meeting in reference to the publication of a reprint of the *Pharmacopœia*, and of certain additions, in the form of a supplement, have been carried out.

"Five thousand copies of the reprint have been prepared, and with them a corresponding number of the additions have been bound up for sale, without any addition to the price of the work.

"Ten thousand copies of the additions have been bound separately. The price of these copies has been fixed by the Executive Committee at 9d. each.

"The cost of printing the reprint and the additions, together with the amount paid to Dr. Redwood for preparing and seeing both works through the Press, amounts to £738 18s. 6d.

"Nearly one thousand copies of the reprint, and 6,500 copies of the additions have been sold since publication; realising the sum of £376 13s. 6d., and leaving on hand, stock, the value of which is estimated at £391 16s.

"The Committee beg to recommend that the Pharmacopœia Committee be reappointed, and that it consist of five members.

"They also recommend that the duties of the Committee be to superintend all matters relating to the *Pharmacopœia*, more especially to consider the publication hereafter of a new edition of the work, and of the steps which should be taken for its preparation.

"The Committee beg to state that there are no outstanding liabilities on account of the *Pharmacopœia*.

"A statement of the debtor and creditor account of the reprint and additions of the *Pharmacopœia* is appended.

"W. SHARPET, Chairman.

"July 16th, 1874."

It was now moved by Dr. Sharpey, and seconded by Dr. Bennett, "that the report be received and adopted."

A desultory discussion followed, in which Drs. Apjohn, Smith, Wood, Quain, Bennett, Sharpey, and Storrar, and Mr. Quain took part.

Sir D. Corrigan proposed that the third paragraph, page 5, of the report be omitted.

Proposed by Professor Turner, "that after the word *Pharmacopœia*, 7th paragraph, and page 5, the remainder of the paragraph should be omitted."

Seconded by Dr. Storrar, and agreed to.

Dr. Quain proposed, seconded by Dr. Wood, "That the following Pharmacopœia Committee be appointed: Drs. Quain, Begbie, Bennett, Sharpley, and Smith."

Moved by Sir Dominic Corrigan:

"That the attention of the Pharmacopœia Committee be requested to the desirability of correcting, in any future edition of the *Pharmacopœia*, the approximate solubilities of salts and other substances under the head of characters and tests, instead of the present indefinite information afforded in the present *Pharmacopœia*."

Sir D. Corrigan stated he had great difficulty in prescribing occasionally on account of the solubility of the different salts not being fully mentioned in the present edition of the *British Pharmacopœia*.

Dr. Smith seconded the resolution. Carried.

Dr. Leet proposed; seconded by Mr. Quain:

"That this Council consents to the proposal that the Apothecaries Hall of Ireland be allowed to appoint three examiners, instead of one, in practical pharmacy, under the scheme for the formation of a conjoint examination in Ireland, bearing date the 28th of June, 1872."

Dr. Smith believed the Council had not the power to send what he considered an "instruction" to the Apothecaries Hall in Ireland. The proposal was agreed to.

The President now read a list of examining bodies whose examinations fulfil the conditions of the Medical Council, as regards preliminary education, recommended by the Executive Committee. The Committee recommended that the list be the same as last year, with the addition of "The Oxford and Cambridge Schools Examination Board."

After a short discussion on the subject, Dr. Humphry moved, and Dr. Storrar seconded:

"That in addition to the examinations already recognised by the General Medical Council, the junior local examinations conducted by the English universities should be recognised for the preliminary education of medical students, provided that Latin and mathematics—and also one of the following optional subjects, viz., Greek, French, German, natural philosophy, including mechanics, hydrostatics, and pneumatics—are among the subjects included in the pass certificate."

Moved by Dr. Humphry and seconded.

Dr. Humphry said: "It may appear somewhat informal to bring the matter forward in the present manner, but on account of causes to which he might allude, he considered it advisable to do so." Having read a report of a committee of teachers suggesting there should be less diversity of examinations, and that examining boards should examine in the preliminary of medical students, he forcibly put his views before the Council.

A discussion followed, in which Drs. Quain, Acland, Begbie, and Sir Dominic Corrigan, Dr. Storrar, Professor Turner, Dr. Wood, and Dr. Parkes took part. The motion was carried.

On the motion of Dr. Wood, seconded by Sir D. Corrigan, an adjournment of twenty minutes was agreed to.

Moved by Dr. Bennett, seconded by Dr. Bradford:

"That the Council do express their satisfaction at learning from the statement of the President, and by the documents laid before them by the Representative of the Royal College of Physicians of London, that the arrangements for carrying out the scheme for a conjoint examining board for England are so far advanced as to render it probable that the scheme will be in operation during the present year; and that, with the exception of the Society of Apothecaries, all the English licensing bodies have concurred in the scheme, and have appointed their representatives on the Committee of reference, by whom the necessary regulations have been framed. The Council are further pleased to learn that the Society of Apothecaries have obtained by a recent Act of Parliament the means they required to enable that body also to join the scheme, and thus to fulfil the desire expressed by the Council in their minutes of March 1, 1872, that the scheme as

sanctioned by them should be rendered a complete scheme for a conjoint board for England."

In doing so, he stated that now the Act of Parliament had been passed authorising the Apothecaries' Society to join in the conjoint scheme all difficulties were removed. Carried.

Moved by Dr. Humphry, seconded by Dr. Wood, and carried:

"That the executive Committee be requested to revise the "recommendations and opinions of the General Medical Council; to incorporate with them resolutions 2, 3, 4, 11, and 12, (see minutes, pp. 51 and 60), and to forward the recommendations and opinions so amended to the several licensing bodies." Agreed to.

The report of the finance Committee was then read by the Secretary.

#### "REPORT."

"The Finance Committee beg leave to submit to the Council a statement of the *income* and of the *expenditure* of the Council during each of the years 1872 and 1873, and of the estimated *income* and *expenditure* for the year 1874.

"It will be seen that the actual *income* for the year 1873 was less by the sum of £768 16s. than that of the year 1872. This difference is almost entirely due to the exceptionally large amount of fees received for registration by the several Branch Councils in 1872, and not to any special decrease in the *income* of the year 1873, which was not below the average. It will also be seen that the balance in favour of *income* in 1872 was £2,260 8s. 7d., whilst in 1873 the balance amounted to only £212 17s. 6d. This difference is due to the fact of the Council having sat during only five days in 1872, whilst in 1873 the sittings of the Council extended to nine days; further, it will be observed, that a sum of £598 10s. has been expended in 1873 on account of the visitations of examinations. On this point the Committee think that it may interest the Council to know that a further sum of £301 18s. has been paid on account of these visitations, which will be included in next year's account, making the entire cost of the visitations £900 8s.

"With respect to estimate for the present year, the *income* will probably not be less than that of the preceding year, whilst the estimated *expenditure* has been necessarily increased to meet the charges which will accrue in connection with the occupation of the new premises.

"The Committee beg to mention that they have received a letter from the Clerks to the Council, Messrs. Bell and Roope, which they have referred to the Executive Committee, who have authority to deal with the subject of the letter, in accordance with the minutes of the General Council, April 3, 1873.

"RICHARD QUAIN, M.D.

"July 17, 1874."

Proposed by Dr. Sharpey; seconded by Dr. Flemming:

"That the report be received and entered on the minutes." Agreed to.

Proposed by Dr. Quain; seconded by Sir Wm. Gull:

"That the report be adopted." Agreed to.

The President announced the programme ended, and the time had come, when—

Sir Wm. Gull now rose and said: "Before you proceed, Sir, will you allow me to read this document which I hold in my hand. It has been unanimously signed by the Council. [Sir Wm. Gull then read the document, which stated the wish of the Council that Dr. Acland might be induced to act as President.]

When Sir Wm. Gull had completed the reading of the paper—

Dr. Paget rose and said, that he was aware for some days past of the desire of the Council, nevertheless, he felt it would be quite out of his power to deviate from his previous determination. The sheet of autographs placed in his hands he should certainly consider to be one of the most precious documents he possessed. He felt acutely the pain of separating from colleagues with whom he had worked so long and so harmoniously. With the deepest thanks, that he could not sufficiently express, he should retire, and the two keys of his office he should hand to Dr. Stokes for his successor. [Dr. Paget handed the keys to Dr. Stokes, shook hands with the members of the Council most warmly, and then retired.]

Moved by Dr. Wood, seconded, and carried by acclamation:

"That Dr. Stokes take the Chair."

Dr. Wood rose and proposed:

"That this Council cannot part with their late President, Dr. Paget, without expressing to him their great obligations for his services as their President, services which have been so

ungrudgingly devoted, at large sacrifices to himself, for the good of the Council and the profession—for the uniform courtesy of his demeanour—for the impartiality of his decisions—for the discretion of his conduct in the chair—which have secured for him the esteem and affection of the members of the Council, and have conduced greatly to the efficiency of the action of the Council in raising the status of the medical profession."

Seconded by Sir D. Corrigan, and passed amid enthusiastic applause.

At this juncture the reporters were desired to retire. Dr. Acland preceded them on their readmission, when Dr. Stokes informed him that he had been elected President. Having taken the chair he thanked the Council for the great honour conferred upon him. He regreted the retirement of Dr. Paget. He spoke of the great services rendered the Council by Sir B. Brodie, Mrs. Greene, Burrows, and now, the late President. He should not forget the responsible duties they had placed upon him. After sixteen years in connexion with them, and thirty years of his public life, he should follow the footsteps of his predecessors.

Dr. Smith proposed:

"That the powers and duties heretofore delegated to the executive Committee shall be vested in the said Committee until the next meeting of the General Medical Council."

Dr. Begbie seconded this resolution. Passed.

Moved by Dr. A. Smith, seconded by Dr. Begbie, and agreed to:

"That the cordial thanks of this Council are due and are hereby tendered to Dr. Andrew Wood, for his services as Chairman of the business committee during the present session of the Council."

Moved by Dr. A. Smith, seconded by Dr. Begbie, and agreed to:

"That the thanks of the Council are due, and are hereby tendered to the Treasurers, Dr. Quain and Dr. Bennett, for their important services."

After the transaction of a small amount of routine business, the Council adjourned. Hand-shaking, warm and hearty, accompanied by congratulatory expressions mutually and reciprocally interchanged, commenced, and ere the clock previously alluded to told the fifth hour silence reigned supreme beneath that dome where good nature, good temper, and shrewd capacity for debate revelled so recently. In verity might the retiring members of the Council address each other in the words of the poet, judging from their looks and actions, on their egress from the scene of their recent labours:

"Had we never loved so kindly,  
Had we never loved so blindly,  
Never met, and never parted,  
We had ne'er been broken-hearted."

## The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 22, 1874.

### HARVEIAN ORATION.

#### II.

It may not be amiss to gather a few interesting notes from the oration respecting which we spoke in our last article; for the later life of Harvey is quite as interesting as the earlier, to which we confined our remarks in our previous article. Dr. West remarked that one dares not, in an oration to commemorate Harvey, omit, how superfluous soever the mention may be, some brief statement of what his great discovery was. It was twofold:—

1. After corroborating the statements of those who had denied either that blood transudes through the walls of the ventricles, or that the pulmonary veins bring back to the left side of the heart air commingled with the

blood, he asserts that the left ventricle has no other function than that of impelling the blood brought to it through the arteries, which themselves contain blood and nothing else, not air, nor vital spirit, but blood purified by its passage through the lungs, and so made apt for the nourishment of the whole body; and

2. That while the arteries thus distribute everywhere the fresh pure blood, the veins with which they communicate bring back that same blood, no longer pure, to the right side of the heart, whence it is once more transmitted to the lungs, thence carried again revived to the left ventricle, and then once more distributed throughout the body, its changes not being those of an ebbing and a flowing tide, but the ceaseless current of an onward rushing river.

We have no means of tracing step by step Harvey's progress, or of knowing when the grand simplicity of the circulation of the blood first revealed itself to him as unquestionable truth.

Moreover of Harvey's inner life we have no record; he taught the doctrine of the circulation of the blood as early as 1615, when he held the office of Lumleian lecturer, but it was not until 1628, when he was fifty years old, that he gave to the world the full fruit of his labours, in his *Exercitatio de Motu Cordis*, which was published at Frankfort-on-the-Main. Dr. West finds few scientific treatises so interesting as this, whether one reads it in Harvey's own Latin, or in the most excellent translation of Dr. Robert Willis, and what first strikes him in reading Harvey's essay *On the Motion of the Heart*, and still more in his two letters, written years afterwards, to the younger Riolaus who had attacked his doctrine, is the exquisite courtesy of his tone towards his opponents; it is the more remarkable, since it was so little the custom of the time.

The next point brought out by the orator for 1874 is the query—What was the practical outcome of it all; what was the use, the good of the discovery of the circulation of the blood? Four years before the *Novum Organon* appeared, Harvey had anticipated its famous lesson, "*Non fingendum aut excogitandum quid natura faciat aut fiat*," and had proved beyond the possibility of refutation, what years afterwards he asserted in eloquent words, "That facts cognisable by the senses wait upon no opinions, and that the works of nature bow to no antiquity; for indeed there is nothing either more ancient, or of higher authority than nature." Still, was human life prolonged, human suffering mitigated, as the direct and immediate consequence of the discovery? To both these questions Dr. West admits we must answer *No*; but the *no* must be accompanied by two qualifications.

"1st. In the ordinary affairs of human life many things are done rightly, but on wrong, or at least on insufficient, grounds, just as in the world of morals many a man is diligent, or temperate, or chaste, on grounds far lower than the noblest. The seaman still navigated his ship in the main correctly by the stars nearly three hundred years after the use of the mariner's compass was known in Europe, and treatises on the use of the astrolabe continued to appear down nearly to the end of the sixteenth century. The Ptolemaic theory of the solar system was wrong, but it served to calculate eclipses by as well as the Copernican.

"But 2nd. We, with our narrow span of life, are

naturally in a hurry for results. What comes not in our own time seems delayed indefinitely, and we feel as little children do when they dig up the ground in their impatience to learn whether the seeds they planted have yet begun to sprout. It was thus once supposed that in the realm of nature effect followed cause in quick succession, and it was little thought how slow is the action of those powers which have by their continuance upheaved mountains, or have hollowed out deep seas. So, too, in the world of intellect the remote consequences of a discovery are long in disclosing themselves, impossible to be foreseen. No gift of second sight showed at the time to anyone the electric telegraph in Franklin's experiment made a hundred and twenty years ago. Harvey admired the skill of the artificer revealed by his researches as it had never been before; but of the practical results of those researches he saw but little; and could never have imagined with what accuracy we can now, thanks to his labours, ascertain the nature and seat of disease in each of the four cavities of the heart itself, preface its course, and even where we cannot cure, obtain at least an euthanasia for our patient, and rob death of half its terrors by depriving it of more than half its suffering."

The next part of the oration spoke of Harvey as a physician, and we fully agree with the suggestion that his fame as a discoverer has eclipsed his merits as a practical physician, and these could have been of no ordinary quality. Then came the benefactors of the College, who are always to be commemorated, but Dr. West discarded the notion that there were those who gave a little money, holding them to be those who have left the inheritance of an example, and so he spoke of Sydenham, Jenner, and Bright—men diligent in seeking the ways of nature by means of experiment, even as Harvey had done. This brought him to the objections sometimes said to exist to science as possibly opposed to religion, on which he declared that such objections as there are attach not to the facts observed, but to the inferences, the generalisations drawn from imperfect knowledge.

## Notes on Current Topics.

### The Edinburgh Chair of Physiology.

As we some months ago predicted would be the case, Dr. Hughes Bennett has now, owing to failing health, resigned the Chair of Institutes of Medicine and Physiology in the University of Edinburgh, and in him the great northern school of medicine loses a "bright particular star," whose place in the professorial firmament it will not be easy to supply. Several eligible candidates have, however, already offered themselves to fill the vacant chair. Professor Cleland, of Queen's College, Galway; Professor Rutherford, of King's College, London; Dr. McKendrick, Physiological Assistant in the University of Edinburgh; and Dr. Bell Pettigrew, Pathologist to the Royal Infirmary of Edinburgh, are all candidates, and have all high qualifications for the office which they seek. Dr. McKendrick has the special claim that he has for three winters past read Professor Bennett's lectures to his class; and Dr. Pettigrew may well urge that he is an original discoverer and a skilled lecturer, and that he has acquired a more than European renown. To us it seems that it will be difficult for any other candidate to produce a catalogue of honours and achievements at all comparable with that

which is contained in the address which Dr. Pettigrew has issued. The curators of the University of Edinburgh are men of culture and discrimination, and they will not fail to perceive who of the candidates is most deserving and most promising. For our part we have little doubt as to the result of the contest.

### The Water Supply of our Towns.

THE Local Government Board has issued a very important document to the various local sanitary authorities on the subject of a pure and wholesome water supply. The long continuation of dry weather renders this step particularly necessary at the present moment, since it may tell seriously upon the public health. The mode of water storage is also a question which demands attention. The open reservoir system is still permitted to exist in country districts, although it is known to produce serious contamination and favour the growth of animal and vegetable life. Open storage has been prohibited for years in the metropolis. Why Parliament should make one law for London and another for the densely populated provincial towns, where the same evils exist only in a less exaggerated form, it is difficult to say. At the present moment a dispute is going on, and a considerable amount of acrimonious feeling is being displayed, about the water supply of Wakefield. An action has also just been concluded on the question of the open reservoir storage of water for the town of Folkestone, and in which a highly respected member of the profession, Dr. Bowles, recovered heavy damages (£1,000) against the Secretary and Solicitor of the Water Company for defamation of character.

The circular alluded to above runs as follows:—

"I am directed by the Local Government Board to state that, in consequence of the long continuance of dry weather, their attention has been drawn to the fact that in several parts of the country the ordinary water supply has become considerably diminished, and there is reason to be apprehensive that, as the summer advances, the evils arising from this cause will be much more seriously and extensively felt. Among such evils must be included the very serious danger to health which will arise if, for want of a better supply, recourse is had to polluted water.

"Under these circumstances, the Board think it right to point out to the sanitary authority the importance of taking steps to inform themselves fully of the nature and extent of the existing water supply in the several parts of their district, and the sources which may be properly relied upon for the purpose of supplying any present or prospective deficiency.

"The Board need scarcely remind the sanitary authority that one of the chief duties which the Legislature has imposed upon them is that of providing their district with a sufficient supply of water, and the Board cannot too strongly impress upon them the expediency, at the present time, of adopting every available precaution for the storage of wholesome water in those localities which are likely to suffer from drought.

"With this view it is desirable that the sanitary authority should make a careful examination of the existing sources of supply, so that they may, as far as practicable, be economised, and that steps may be taken where necessary to obtain an additional supply.

"If any part of the district is within the limits of a water company, the attention of the company should, with the like object, be directed to the points lastly referred to.

"The sanitary authority are aware that if there is no such company, they themselves may not only construct and maintain water works, but also dig wells, and do any other acts necessary for providing a water supply for their district.

"It is, therefore, competent for them, in case of need, to provide, by means of water carts or other like expedients, a temporary supply for domestic use, and for flushing sewers and drains; and the cost attendant upon the adoption of this suggestion, which would be comparatively small, might be wholly or in part reimbursed by a moderate charge for the accommodation."

"I am directed to add that the greatest care must of course be taken with regard to the purity of the water which the sanitary authority distribute; that no supply should be used which is not perfectly safe from pollution by excremental matters or other filth; and that other impurities, if the water contains such, should be removed from it by filtration, or otherwise, before it is delivered for domestic use."

### Spectrum of Muscle.

M. RANVIER communicated on the 1st June to the Paris Academy of Sciences a note on the spectrum given by the striæ of muscles. He said a spectrum is always given by muscle, whether in a state of rest or activity. Contrary to the statement of Merkel, he says the transverse situation exists in every physiological condition of muscle. He adds that certain muscular lesions deprive the tissue of the property of giving a spectrum.

### The New Hospital for Women.

SOMEONE has sent us No. 6 of *Women and Work*, a new weekly, edited by Miss Faithful. Among other interesting matter is an account of the meeting held on behalf of the hospital established by Mrs. Garrett-Anderson, who has for some time been assisted by Miss Morgan, now Mrs. Hoggan.

Mrs. Anderson made a good speech, except that she pretended that there was loss of modesty in "servants from the country" talking to a medical man before students.

### Fradelle and Marshall's Exhibition of Photo-mezzotint Portraits.

THIS gallery, which has now existed for three years, is essentially a National Portrait Gallery, and is divided into a series of sections which include the names of most of those who are distinguished in art, science, law, and literature.

It is, however, with the medical section that we are principally concerned, as we believe that there are many members of the profession who are not yet aware of the existence of this gallery.

The catalogue contains upwards of one hundred portraits, and includes a number of the staff of the different London hospitals. King's College is represented by Professor Bentley, Dr. Guy, Mr. Henry Smith and others, all of which are striking likenesses. We were sorry to notice the absence of Sir Wm. Fergusson and his distinguished pupil, Professor Wood. Guy's and St. Thomas's are well represented, and the pleasing and characteristic likenesses of Mr. Bryant and Mr. Le Gros Clarke will at once be recognised, though, in our opinion, one of the happiest efforts in the whole gallery is the likeness of Mr. Francis Mason; the natural expression has been exactly caught; the pose is easy, and the light and shade so nicely balanced that we are compelled to admit that these clever artists, by their new method of mezzotint, are able to produce more truthful and softer likenesses than

by the ordinary method. Bartholomew's, Westminster, Charing Cross, and indeed, all the London hospitals, have their representatives; and we strongly advise those who have not yet visited the gallery to do so, as they will meet there with many old friends, and which cannot but fail to give rise to pleasant reminiscences.

When Mr. Marshall showed us round he informed us that he and his partner were endeavouring to complete the gallery by the opening of the winter session in October next.

Just prior to leaving, our attention was drawn to a new section they have lately added. The Indian—which already contains a long list of civil and military officers, and excellent likenesses of Drs. Forsyth, Leckie, Fayrer, and Gordon.

### Liability of Medical Practitioners to Consultants.

A VERY interesting trial has just taken place at Warwick in which is involved the right of a consultant to be paid without a definite contract to that effect.

The children of a Mr. Booth Mason took scarlatina, and his wife, who was in her confinement, took it from them, and died. Mr. Fenn Clarke, a general practitioner, attended the family during these occurrences, but when Mr. Booth Mason himself was attacked with symptoms of the disease, and, as was sworn, became delirious, he (Mr. Clarke) thought it right to call for other advice. Accordingly he summoned Dr. Carter, a consulting physician of the locality, and his attendance, beginning when the patient was incapable of expressing his wishes on the subject, was afterwards continued without objection, along with Mr. Clarke, when the patient was improving, and quite capable of giving directions. After his recovery, Mr. Booth Mason refused to pay Dr. Carter, alleging that he had not asked him to come, and that he considered that he attended simply to oblige and reassure Mr. Clarke. The Judge, after hearing evidence, pointed out that there was nothing to show that Mr. Clarke did not call in Dr. Carter on his own account. According to the case *Veitch v. Russell*, reported in Russell's "Law of Contracts," a physician could not recover unless a contract was actually made. The evidence does not show that Mr. Clarke communicated to the defendant that he had called in Dr. Carter, and that he thought it necessary to do so. If in answer to that Mr. Mason had said "You are quite right in doing so," it would have implied a contract. At present there is nothing to show that Mr. Mason ever gave his assent to receiving the visits of Dr. Carter in the ordinary way of a physician expecting to be paid for his attendance. Counsel for Dr. Carter referred to a case which was heard some time ago before Sir William Page Wood, sitting as Vice-Chancellor, in which he thought the law on the point was very properly stated. From the case it appeared that a physician under such circumstances would be entitled to recover, the patient having adopted his attendance, although he gave no express order for him to be called in. His Honour admitted that the authority he had cited was a book published in 1853. Mr. Sanderson said the case was referred to in the judgment in the Vice-Chancellor's Court to which he had referred, and did not appear to have been thought of any

value. His Honour said he was not aware of any modern case in which the point had arisen. Mr. Sanderson read an extract from the "Medical Directory" of 1874, which non-officially gave the substance of a recent decision to the effect that a physician was, in the absence of a distinct understanding to the contrary, to be entitled to recover in all cases for his attendance. His Honour adjourned the case for Mr. Sanderson to search out the authority on which this ruling was founded.

#### Court Hospitalities to the Profession.

WE observe that the honour of invitation to Court is not dispensed by the Lord Chamberlain on the same principle that is assumed by the gentleman who fills the analogous office at Dublin Castle. Though it was considered proper to exclude the physicians and surgeons to her Majesty, in Ireland, from the hospitality of the Duke of Abercorn, we are gratified to observe that, at head-quarters, the Queen's medical officers are judged worthy of a place beside her Majesty's servants of other professions. Sir William Jenner, Sir James Paget, Sir William Gull, Dr. Sieveking, Dr. Lowe, and Mr. Prescott Hewett were among those who had the honour of receiving invitations to the State Ball given at Buckingham Palace. Probably as it has been decided by Sir Michael Hicks Beach that Irish medical men are unfit to hold the Commission of the Peace; and as the Crown seems to think that distinguished members of our profession in Ireland are worthy of the same titular distinctions which are showered upon those of England and Scotland, we must be prepared to be told that while London physicians and surgeons are fit companions for Royalty, their Dublin brethren are not fit to breathe the same air as the Viceroy.

#### Water for Soldiers.

THE sanitary ardour of the Irish military authorities does not appear to be as great as could be desired, for we find that for the fourth time Dr. Cameron has been obliged to report an examination of the barrack water at Ennis of so unfavourable a character that it surprises us that the militia garrison of that town has escaped a serious epidemic of typhoid fever or dysentery. Dr. Cameron says:—

"The water from the pump at the militia barracks, Ennis, has been analysed by me upon four different occasions, and on each I reported that it was exceedingly bad. It contained 162·81 grains of solid matter (including 37·81 grains of organic and volatile substances) per gallon, and the ammonia amounted to nearly two grains per gallon, about a thousand times as much as is found in the Thames water at London Bridge. *I never examined so foul a water before or since.*"

It is eminently disgraceful to the authorities that the condition of the water supplied to the soldiers has been reported three times without receiving any attention from them.

#### Adulteration Law.

IN their report to Parliament, the Committee on the Adulteration Act have taken up the position which all sensible men may be expected to occupy, and which the MEDICAL PRESS AND CIRCULAR has adopted all through the controversy. The Committee simply enunciates the

principle that the buyer should be allowed to buy anything and the vendor to sell anything so long as it contain no deleterious ingredient in toxic quantity, and so long as it is not sold under a fraudulent name, but is truly and honestly described to the purchaser by the label upon it. As to the admixture of poisonous ingredients, the Committee report that these additions to articles of food are neither usual nor large in quantity, and they imply that as a rule little control will require to be exercised by the Legislature over this form of adulteration. As to the addition of innocuous matter, either for the improvement or the cheapening of any article of food, they express their opinion, and it is a very just and reasonable one, that these additions should not be condemned or punished as long as the purchaser is honestly and truly informed of the nature of the admixture. Parliament should, however, insist on this latter requirement being fulfilled, for the attempt will undoubtedly be made by manufacturers to veil the sophistication of their wares under some vague name which will afford no information whatever to the consumer.

We have already experience that they continue to designate the mixture of carbonate of soda and citric acid as "Effervescing Citrate of Magnesia," because they know that the public would not buy it if they knew that it did not contain an atom of magnesia.

As we have from the first very earnestly advocated the enactment of the law against trade frauds, and defended the operation of the Adulteration Acts against the objections of dealers who came within its penal clauses, we are gratified to learn from the report of the committee that, in their opinion, the law against adulteration had already effected much good, and would yet prove to be of great benefit to the public.

#### Frederic Bird Memorial.

A MEETING of the friends and former pupils of the late Dr. Frederic Bird was held in the Board Room of the Westminster Hospital on the 6th instant, to consider the establishment of a memorial to one who for many years held the post of obstetric physician to the Hospital and teacher of midwifery in the Medical School. It was determined that the memorial should take the form of a prize, exhibition, or scholarship in connection with the School. An influential committee was appointed, with Mr. Cowell as honorary treasurer, and Dr. Potter as honorary secretary.

#### Society of Medical Officers of Health.

THE report of this Society on the statistical returns in the annual reports of medical officers of health states that the society is unanimously of opinion that it is desirable the statistical returns of all medical officers of health in England and Wales should be based on a uniform system. It contains also a series of tables as skeleton models, which it is hoped will be adopted by all medical officers of health. The tables are no doubt susceptible of improvement; but their adoption in the present form is urged, as it is believed that any disadvantages they may possess are outweighed by the advantages resulting from a uniform system which admits of the direct comparison of the statistical returns of two or more districts. It is not intended that these

tables *only* should be used by the medical officers of health, but that at least the information given by them may be given for all districts, and in the same form.

It is thought desirable, and asked, that

1.—All statistical returns be made out to the end of the registration year, as defined in the registrar-general's reports (Dec. 31st, or thereabouts).

2.—That, merely for the sake of uniformity and convenience of compilation, the headings of columns for tables be as far as possible identical with those used in the registrar-general's tables.

3.—That the numbers of the tables adopted by the society be in all cases appended to these tables when used; and that, to avoid confusion, different numbers be assigned to any other tables which it may be thought fit to insert in an annual report.

We hope these recommendations will be generally adopted.

### The Mecca Pilgrimage of 1874.

DR. BUEZ, writing to the *Gazette Hebdomadaire*, from Djeddah, reports that the pilgrimage has been accomplished this year under the most favourable conditions as regards the public health; so that if Europe is to suffer from an attack of cholera this summer, it will not be due to a new importation from India. It cannot be doubted, he observes, that the manifestations of late met with in Europe are but recrudescences, or remains of the great epidemic of 1864-65, which left ill-extinguished foci in several localities, capable of being again brought into activity by favourable conditions, but always manifesting a decreasing vitality; so that if a renewed importation can be prevented, such foci will gradually die out.

### Wine and Whisky for Irish Paupers.

DR. CAMERON, county analyst for Sligo, reports to the Grand Jury that specimens of milk examined for the Dromore West and Sligo Unions were found to have been adulterated with 12 per cent. of water. For the same union he analysed a specimen of wine, which he found to be supurious, and unfit for use, and a specimen of whisky of inferior quality, scandalously diluted with water, and containing only 38 per cent. of alcohol or spirit.

### Flogging Schoolmasters.

A WEEK ago we directed attention to a melancholy case of flogging, and where the schoolmaster, mistaking disease of the brain for stupidity, forthwith proceeded to cure it by administering the rod, and only discovering his mistake when the boy lay dead before a coroner's jury. It would be well if schoolmasters would bring a little reason to bear upon the dull or stupid ones among their pupils, as by a timely appeal to the doctor, or a judiciously administered dose of medicine, he might spare himself some trouble and the remorse of being accessory to the death of a stupid one. At all events, the public would be spared the pain of reading such scenes as that reported in the daily journals as occurring between a Mr. Lucas, a village schoolmaster at Minney, and a Mrs. Nicholson. It appears that the schoolmaster flogged the son of the latter, whereupon the enraged

mother took the law into her own hands, and was ultimately convicted of an assault. On Friday last, however, she met and attacked the schoolmaster, and forthwith proceeded to pull his whiskers, whereupon, and finding he could not so easily shake off his assailant, he beat her on the head with a heavy whip so brutally that the poor woman has remained insensible ever since, and will, it is expected, not recover. Poor Mr. Lucas has since been apprehended on a charge of manslaughter.

### The Forthcoming Meeting of the British Association for the Advancement of Science.

THE Local Executive Committee have issued a circular reminding the members that the next meeting of the Association will be held in Belfast, commencing on Wednesday the 19th of August, under the presidency of Professor Tyndall.

The town and neighbourhood of Belfast present many objects of general and special interest. Those who wish to see the progress of certain branches of modern industry will be gratified by visiting the various establishments in which the manufactures derived from flax in every branch are conducted upon the largest scale. The large machine works and iron ship-building yards of the town will also repay a visit.

The mineral resources of the county of Antrim, in which Belfast is situated, have recently received a new and unexpected development, and the utilisation of its large beds of peat is a problem which it is now attempted to solve.

The whole province of Ulster is full of objects of the highest interest to the admirer of natural scenery, to the geologist, the naturalist, and the antiquarian; and many of its most interesting localities, such as the Antrim coast, the Giant's Causeway, the Mourne Mountains, Lough Neagh, the Round Towers of Antrim and Drumbo, are within an easy distance of Belfast.

WE regret to announce the decease of Dr. Wilson, of Devonport, from blood-poisoning through a wound in performing an operation at the Royal Albert Hospital.

It is announced that competitive examinations of candidates for admission into the Medical Services of the Army and Navy will take place at the University of London on Monday, 10th August, 1874, at 10 o'clock.

AT a late meeting of the Executive Committee of the London Hospital Saturday Fund, Lord Brabazon mentioned that several active gentlemen were undertaking to devote themselves to promoting the success of the movement. It was also announced that money in aid of the Working Men's Collection for the 17th October next was being subscribed in various firms.

THE annual general meeting of the Medico-Psychological Association will be held at the Royal College of Physicians of London, on August 6th, under the presidency of Thomas L. Rogers, M.D.

THE Council of the Pharmaceutical Society of Great Britain will give a *conversazione* to the members of the British Pharmaceutical Conference, at their house, on Wednesday, the 5th of August, at eight p.m.

MR. SCLATER-BOOTH stated in the House of Commons the other night, that when the Sanitary Laws Amendment Bill became law, a circular would be issued to all local authorities explaining its provisions.

DR. LETHBRIDGE was re-elected President of the Association of Medical Officers of Health at their annual meeting, held on the 8th inst. Dr. Stevenson having retired from the joint secretaryship, Dr. Corfield was elected to the vacant office.

MR. JOSEPH PRESTWICH, F.R.S., has been appointed to the Chair of Geology at Oxford, as the successor of the late Professor Phillips. The new Professor received the Geological Society's Wollaston Medal in 1849, and was elected President of the Society in 1870.

THE Metropolis Slaughter Houses Bill is now in committee of the House of Lords. Various amendments and suggestions have been proposed by the Association of Medical Officers of Health, and pressed upon the Government through Sir Selwin Ibbetson.

It is proposed to establish a Chair of Biology, combined with Physiology, in connection with the Durham University Colleges of Medicine and Physical Science, Newcastle-upon-Tyne, in October next. The salary will be £450, with a portion of fees. Candidates for the office are invited to apply, with testimonials, to Theo. Wood Bunning, Secretary to the College of Physical Science, Newcastle, before the 15th of August next, from whom full particulars as to duties, &c., may be obtained.

THE *Chemist and Druggist* reminds us that a new Alkali Act has passed the House of Commons, the object of which is to increase considerably the stringency of the present laws respecting the escape of muriatic acid and other noxious gases. The House of Commons, too, has passed a Bill to amend the English Apothecaries' Act. It empowers the Apothecaries' Company to strike off from their list of licentiates the name of any person convicted of crime, or who shall, after due inquiry, be judged by the Medical General Council to have been guilty of infamous conduct in any professional respect. A clause declares that nothing in this Bill is to deprive the Apothecaries' Company of such right as they now have, or relieve them from any existing obligation, to admit women to the examinations for certificates to act as apothecaries, or to enter on the list of licentiates women who have qualified to be registered.

THE results of Hospital Sunday in London, says the *Chemist and Druggist*, have turned out better than was at first feared. Upwards of £8,000. has been already paid in—a little better than last year. Her Majesty has

declined to repeat her last year's donation of 100 guineas. Among the curiosities of the collection was the sum of 15s. collected after an earnest appeal from Mr. Jabez Inwards in aid of the Temperance Hospital, which, having been but recently established, would not have otherwise shared in the public liberality.

CONTRARY to expectation, the committee appointed to consider and report upon Mr. Errington's Pharmacy Bill, of which we have published the text, has already commenced taking evidence. We understand that Sir Dominic Corrigan, Dr. Leet, Dr. Collins, Mr. Hayes, and one or two others, have been examined. This promptitude on the part of Government shows an earnest desire to do something, although it is too much to expect that any new measure can be introduced this session. We have not heard that the Committee has summoned as witnesses any of the medical practitioners, or teachers, who in Ireland are known to be conversant with the pharmaceutical wants of the country or the educational status of the Apothecaries Hall and there appears to be a danger of the Irish Pharmacy question being dealt with on very insufficient information.

DR. MACKERN, in his letter to the Medical Council, complaining of an individual who held club appointments in Long Eaton, Nottingham, without any legal qualification whatever, stated that when he spoke to some members of these clubs as to the illegality of employing such a man, they replied that it was not his business if they were satisfied, the fact being that they were so ignorant as to be unable to recognise any difference between a qualified medical man and a quack.

MR. GATHORNE HARDY, in the House of Commons, in replying to a question of Sir E. Wilmot, in reference to filling up vacancies in the medical staff of militia regiments, has declared that all such appointments had been suspended until the regulations as to the status and pay of these medical officers had been issued. These regulations he believed would shortly be brought out. As to compensation to those officers who up to the present time could show any loss or hardship, he could only say that, as in former cases, so also in these, each one would be considered carefully upon its own merits.

## Correspondence.

### THE HARVEIAN ORATION.

TO THE PUBLISHER OF THE MEDICAL PRESS AND CIRCULAR.

20 Austin Friars, London, E.C.,  
20th July, 1874.

SIR,—We are instructed by the Editor of the *British Medical Journal* to write to you under the following circumstances:—

In the last edition of your paper appeared a letter from Dr. Charles West, containing statements which were libellous, and for the publication of which you have therefore made yourself responsible to the Editor of the *British Medical Journal*, to whom those statements referred.

In any event it would have been proper for you to have endeavoured to ascertain whether there was any foundation for the charges made by Dr. West before you published his letter.

But in the *British Medical Journal* published on the 11th inst. (four days before the publication of your paper) a complete denial was given to Dr. West's assertions by the Editor of the former paper. That such a denial had been given we are advised that you must have known, or had ample means of knowing, before you published the letter complained of.

You had therefore the opportunity either of abstaining altogether from publishing the letter, or of simultaneously publishing with it the contradiction which had been given to the statements in it by the Editor of the *British Medical Journal*.

We have therefore now to call upon you to express your unqualified regret in the next edition of your paper for the course which you have taken, accompanying it by the publication of the paragraph from the *British Medical Journal* of the 11th inst. to which we have referred; or we must hold you responsible for the course you have taken.

We are, Sir, your obedient servants,

UPTON JOHNSON & CO.

[REPLY FROM THE PUBLISHER.]

I, ALBERT ALFRED TINDALL, Publisher, to whom the foregoing letter is addressed, beg to say that Dr. West's letter being addressed to the Editor, did not come under my department, that I rarely see the *British Medical Journal*, and did not read the contradiction referred to. I cannot therefore express regret for that about which I had no previous knowledge. Further, that as the foregoing was not received by me until Monday afternoon, as we were going to press, and after the Editors had finished their work for the present number, I had neither time nor opportunity of communicating with them. I therefore append this reply without advice or consultation with any person, and hope the Editor of the *British Medical Journal* and his solicitors will be satisfied therewith.

#### THE COMING EXAMINATION FOR THE ARMY MEDICAL SERVICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Now that announcements are appearing in the various journals regarding examinations to be held early next month for the above services, I think it the duty of all graduates of our Colleges who are already holding commissions in the Army and Naval Medical Services, to do all in their power to warn off intending candidates among their qualified brethren from presenting themselves as candidates for either the Army or Naval Services.

No one can question the advantages to be gained by competition for the Indian Medical Service, for success in admission to this insures rapid and certain promotion, a good position, and an independence hereafter. Not so the British or Naval Medical Service, the members of both of which are now labouring under sad and serious disadvantages, which stand no chance of being remedied while candidates offer themselves for vacancies. To mention all these disadvantages and grievances would take up more space than your journal could allot me; but let me beg of intending candidates to devote an hour towards the perusal of some letters regarding the Medical Service of the Army (British Service) and Navy, which have been published in the last few issues of the *Broad Arrow* and *British Medical Journal*, which will convince them that if success attends their candidature they will come in for little else than grievous disappointment.

Should this letter be deemed worthy of publication I shall feel I have done my duty to those who may (which I may say are sure to) hereafter regret having taken a step they now contemplate doing.

I am yours,

L. R. C. S.

#### THE REPORTS OF VISITORS ON THE IRISH COLLEGE OF SURGEONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The public condemnation of the Royal College of Surgeons in Ireland, both by the visitors of the General Medical Council and by the resolution of censure adopted by the Council itself, will inspire every Fellow and Licentiate of that College with a sense of profound humiliation; nor can any Irishman fail to experience a deep sense of regret that the much-vaunted Irish School of Surgery has, under the auspices of our only surgical corporation, fallen so low as to be compared discreditably with the Glasgow Faculty by a man of so eminent a character as Sir William Gull.

Until the verdict pronounced by the Medical Council is reversed, I, as one of the Fellows, will for the first time feel shame in acknowledging that I hold my highest surgical dignity from a College respecting whose examinations it could be said by any member of the profession that they were "from beginning to end as bad as could be," and that "there never before had been anything brought to the attention of a council of medical men which so painfully showed the utter paltriness of the examination." I earnestly wish that the Fellows and Licentiates of the College could regard such statements as these as the emanations of spite, professional jealousy, or political antagonism; but, unhappily, I find on reference to the medical periodicals that such opinions were approved by a majority of 13 to 3 of the members of the General Medical Council, and are endorsed by the unanimous voice of the medical press of the three kingdoms. I am compelled to accept them as unpalatable truths, and I therefore ask in the name of the Fellows of the College, to whose cause you have from time to time devoted so much attention, Who is answerable to the Fellows of the College for such a state of things?

I hope you, Sir, who have hitherto evinced no hesitation in indicating the existence and cause of other abuses in the College, will not now flinch from answering this question; and should you see fit to do so, I hope that some courageous and independent men will be found amongst the Fellows to undertake the redemption of their College from a dishonour which attaches to every one of us. I enclose my card,

And am, Sir, yours, &c.,

AN INDIGNANT F.R.C.S.I.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Lest you may not be editorially aware of the history of the examination agitation in the Irish College of Surgeons within the last three years, or may not think it incumbent upon you to make public the whole truth upon your own editorial responsibility, I send you a recapitulation of the circumstances which have led to the College, as we say in the army, "losing its good service stripes;" and I claim, from your well-known independence of speech, a full and fair publication of the facts, which I think it is right that the Fellows and Licentiates should be acquainted with.

It is many years since the more advanced educationalists in the Council began to express their dissatisfaction with the system of examination, and to demand its extension and improvement; but their mouths were at all times stopped by the statement put forward by the obstructive party (then a large majority), that if the examination was enlarged the students would at once fly to Scotland for cheap and easy licences, and leave the College to dignified bankruptcy. It appears that this theory is not even yet dead, for I find it to-day in the mouth of the College representative at the Medical Council. Despite this threat the reforming party persisted in their efforts, and at length in 1870 obtained a

committee of council to draw up a scheme for a new system.

That plan was completed by the committee after much deliberation, submitted to the Council, adopted and ordered to be published; and was, in fact, published with the knowledge and consent of the Council. The moment, however, that the proposition for a reform assumed the position of a *fait accompli*, the indifference of the "grinders" and the examiners who, without exception, had all along discouraged any change of the now condemned system, ripened into violent hostility, and every influence was exercised *per fas aut nefas*, to defeat the effort for a reform. Whispers were industriously circulated by some of the hostile section of the Council, that the scheme would never be carried into effect; it was sneered at by a majority of the examiners as unnecessary and impracticable, and it was resisted by the "grinders," even to the extent of absolutely refusing to prepare the students for it, and openly threatening that they would send every man within their influence to Scotland, if the Council persisted in its progressive movement. Meanwhile, in the Council itself, every technical device was made use of by the obstructive party to throw difficulties in the way—to prevent the intentions of Council being made known to the students. Every legal quiddit in the charter was furbished up to show that the scheme was illegal, and every chance of postponement or delay availed of; while, out of doors, the student was threatened that if he presented himself under the new system he would have to meet a hostile court of examiners, who would stick him without mercy. Eventually the "grinders" were driven to get up petitions amongst the students against the new system, which were hawked round and signed by all the raw hands and cronies in Dublin, and then laid before the Council as representing the feelings of the second years' men.

In the face of these efforts the reformed system was persistently urged upon the Council by its advocates, and notably by one active and courageous member, whom you, Sir, wot of; and, at length, the first examination under the new arrangements was held upon thirteen candidates, who had resisted the threats and blandishments which they had had to encounter. Alas! Sir, owing, as was afterwards shown, to an unhappy muddle of the marking on the written examination, and—if it be true, what was at the time loudly said, to the hostility of the Court to the new system—nine out of the thirteen men were plucked, although almost all of them had shown by their *viva voce* examination, a standard of knowledge high above that required under the old system. Under the discouragement of this blow the supporters of reform turned their backs and fled, and the grinders—examiners and make-money-at-any-price councillors—sealed their victory by driving out from the Council the member who had most energetically connected himself with the movement.

Here your readers, and Sir William Gull, have the full and true account of the rise and fall of the only honest effort at reform of examination ever made in the College. It will, I hope, do good if you publish it, to show the profession that the Irish College of Surgeons is not utterly vacant of energetic and independent men of progress, and to remind the Dublin grinders, the examiners, and the dear and easy diploma party in the Council that they, and they alone, are chargeable with bringing the College and its diplomas to disgrace.

Yours, &c.,

A STUDENT OF 1870 WHO KNOWS ALL ABOUT IT.

[We cannot but admit that the foregoing narrative is a "round unvarnished tale," accurate in all its facts, though a little unjust to the examiners and the members of Council. The head and front of the offending of the College is that for fifteen years, while other bodies have been moving a-head in their examinations, it has stuck fast in the slough of ultra-Conservatism, and is to-day

practising a system of examination which might do well enough in the old days of apprenticeship and monopoly, but is utterly behind the age, and short of the requirements of surgical education. The Council are to blame because they have allowed a hankering after the fleshpots of Scotland to prevent them insisting on fair, open, and sufficient examination. The examiners after, in some instances, a quarter of a century's rusting in the old groove, could not be expected to move on without a smart conciliate *vis a tergo*.

The justification of the members of Council who devoted themselves to reform, and especially of the individual member to whom our correspondent refers, who was punished for his zeal by the ostracism of the anti-improvement party, has been swift and complete; and we are gratified to believe that the College will be all the sounder for the severe but necessary ordeal of flagellation to which it has been subjected.—Ed. M. P. & C.]

#### THE REPORT OF THE VISITORS ON THE EXAMINATION OF THE ROYAL COLLEGE OF SURGEONS OF IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

THE not very complimentary remarks elicited at the Medical Council as to the mode of conducting the examinations at the College of Surgeons of Ireland, has, I trust, been of a sufficiently stimulating character as to induce the adoption of some measures of reform and advance on the method of testing. I am quite aware it has often been felt that the *test* was a most uncertain one; good men were rejected while bad were passed, and even those who passed were dissatisfied with the *modus operandi* of their examination; some "pshawed" it as a kind of scrimmage where their real value was unappreciated; others grumbled at being kept the whole time at one or two examiner's little tit-bits; while others admitted they did not know anything well, but had fortunately got up some strong "tips" on the subject asked, and managed to dodge through the time; in fact, the shortness of the time was the chief objection to the well-informed or more modest man, while it was the delight of the ignoramus or of the more astute. The *Lancet* remarks as to another cause of imperfection which, as it states, "did ever any one hear of such an absurdity" as that the examiners must be "gentlemen who are not professional teachers in any school of medicine." This regulation of the College, I believe, is based not as supposed on jealousy, but is to preserve the examination from any appearance of unfair play. I must admit the difficulty as owing to this rule, as the *Lancet* remarks, with but some rare exceptions; the gentlemen selected must be those "who from age or failing powers, or from youth and inexperience are *unconnected with tuition*," and some have continued examiners for nearly a quarter of a century, I think. On the other hand, of what value would be an examination which is to qualify a man for public practice conducted by the lecturers and teachers who taught that same candidate, who received his fees, and would receive possibly more fees if he were rejected, or would receive possibly those of his friends or relatives who may be watching the result of his "pass or pluck" to decide whether they will attend the same teacher's classes. I am quite aware such a method is adopted; but is it a proper system? I am aware myself of a candidate educated elsewhere who was rejected on a certain subject by such an examiner who, when he took out his course and paid his fee to the same examiner, passed that subject with *éclat*, although he himself felt he

knew less about it than before. Without attributing any dishonesty whatever, we know it is probable that a lecturer or teacher will have peculiar views, hobbies, and crotchets which may be practically worthless or singular, and which his pupil will be able to answer, though he might not be a tithe as well informed as a candidate taught elsewhere. The original idea was based, I think, on the proper stratum of knowledge of human nature; but strangely teachers in hospitals were omitted. Now it is amongst hospital surgeons that it appears to me the greatest temptations arise; the pupil is thrown vastly more in contact with the hospital surgeons than even with his regular lecturer; the student has the opportunity of admiring his practice and carrying out his treatment; if this surgeon is of the sanguinary type he has the opportunity of making every thing sweet for his presenting himself for examination by interesting himself amongst his country or town friends in procuring a surgical victim for the special operation, or an illustration of the theoretical ideas of his future examiner. If the surgeon be rather of the *laissez-aller* type, he will take care to ease him as far as possible of hospital trouble, but to sound his praises amongst his friends for consultation or "call me in."

As "a city mouse" I have heard dark hints of such practices, whether they acted beneficially or otherwise, but my now rustic mind can contemplate the difficulties involved. Why not cut the knot by the appointment and suitable payment of examiners, beyond such possibilities,—neither teachers, hospital surgeons, or above all things paid teachers and examiners who qualify for the public service both at the same time? or let a rotatory system be established, with a representative from every school, and thus allow a uniform system and ample testing, before either—as I think have been pretty amply demonstrated by the report of the visitors—condemning a really good man to the blot of rejection or passing an inadequate man from the imperfections alluded to.

Yours, &c., SCRUTATOR.

P.S.—It is to be remembered that the relations of teachers and pupils are vastly different in Dublin and London; the extent of the two cities is so incomparable.

### THE FOLKESTONE WATER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—An English jury having effectually vindicated Dr. Bowles from the libellous and odious charges brought against him by the Secretary of the Folkestone Water Works Company, and the Lord Chief Baron having decided that where the public health is concerned, a medical man may call "a spade a spade," you will perhaps permit me to remark in corroboration of what was said of the condition of the open reservoir of water at this watering place, that two years ago while staying there with a portion of my family, we suffered from repeated attacks of diarrhoea, and, as you may suppose, derived no benefit whatever from our visit—indeed, were rather glad to get away. The weather was then very warm, and the temperature of our bedrooms compelled us to drink a good deal of water during the night, and our children being water drinkers, we partook of a large quantity of the same beverage during the day. However, feeling somewhat better, my son and myself strolled off one morning across the fields, and ultimately came upon a large open circular pond of water, which we soon learnt was the reservoir of the Folkestone Water Works. On attentively examining the water and the large quantity of water weeds, I noticed immense numbers of entomostraca and other infusorial animals feeding upon them, and I at once saw a clue to the attacks of diarrhoea. The water, in short, bore out entirely the character given of it by Dr. Bowles and others, and there cannot be a doubt of its being injuriously contaminated by vegetable and animal growths. Dr. Frankland was perfectly right in saying "that there were not wanting visible causes sufficient to account for the deterioration of the water during its sojourn in the storage reservoirs;" and doubtless, had the Secretary of the Company

possessed a little less pugnacity and a little more common sense, or understood the use of the microscope, he might have recognised in Dr. Bowles, well grounded complaint a desire to protect the health of his fellow townspeople, and prevent visitors precipitately leaving with a bad impression of the salubrity of Folkestone.

I remain, Sir, yours faithfully,

JABEZ HOGG.

1 Bedford Square, London, W.C.,  
June 10th, 1874.

### COMPULSORY SANITARY DUTY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of Wednesday last the 10th Clause of the Public Health Bill begins thus:—"Every medical officer of a dispensary shall be a sanitary officer," &c.

This looks like compulsion, and if so, would you be pleased to point out the clause or clauses containing the penalty or punishment for refusing to accept the office.

It is not likely that gentlemen at or over sixty years of age will be induced to poke their noses into privies, cess-pools, sewers, drains, and all the rest of it, for a few paltry pounds additional to their salaries. The personal and professional degradation of such an office cannot surely be counterbalanced by money, and I intend to employ any or all constitutional means available that will enable me to resist and refuse it, if the present bill becomes law.

A very proper clause in the Act would be to compel dispensary doctors at or over sixty years of age to retire on their full dispensary annual salaries.

A DISPENSARY DOCTOR.

[No penalty is imposed by the Bill. The compulsion upon dispensary medical officers to accept the appointment of health officer was the subject of anxious consideration at the annual meeting of the Irish Medical Association. It was however, considered, that as there is an inspector provided to carry out the most unpleasant part of the sanitary duty, the compulsory acceptance of the office would not be unjust or seriously inconvenient to any one.—ED. M. P. AND C.]

### MEDICAL MEN AND THE COMMISSION OF THE PEACE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your number of July 1st you make reference to a reply given in the House of Commons by Sir M. H. Beach, to a question put to him by Mr. Moore, member for Clonmel, in reference to the nomination to the magistracy of a medical man by Lord Lisamore. The Chief Secretary stated that the Lords Commissioners refused to appoint any medical man in practice to the commission of the peace. A similar case has occurred in County Down. On the 2nd of March last a memorial, numerously signed by nearly all the most respectable inhabitants of the Donaghadee Petty Sessions' District, was presented to Sir Thomas M'Clure, Bart., Vice-Lieutenant of the county, requesting him to nominate and recommend Dr. Stuart, Medical Officer of Donaghadee Dispensary, to the Lords Commissioners for appointment to the magistracy for the district. On the 5th June the following reply was received from Sir Thomas M'Clure:—

"I know the gentleman you refer to is highly respectable and trustworthy, but I may tell you that the Lords Commissioners would not sanction the appointment of any practising doctor, even if only consulting at his own house.

"Thomas M'Clure."

You may make any use you please of this letter.

SAMUEL STUART, M.D.

## Cleanings.

### Phosphoric Acid in the Urine of the Insane.

By DR. E. MENDEL.

AFTER some introductory remarks (*Archiv. f. Psychiatr. u. Nervenkr.* iii. 3., p. 636) concerning especially the quantitative relation between phosphoric acid, the quantity of urine and the solid constituents, and after narration of the cases mentioned in literature, the author proceeds to show that the opposite view, that a greater excretion of phosphorus follows mental labour, is not confirmed by his quantitative examinations of sane and insane patients, since more phosphates are excreted by night than by day during mental activity.

On the other hand he discovered the exceedingly interesting fact that under the same conditions the insane patients excreted *absolutely* less phosphorus and also *relatively* less in comparison with the solid constituents.

As to the urine of so-called progressive paralysis, it is found that in that period of the course of the disease characterised by rapid reduction of weight and sharp appetite, without increase of temperature, the urine is voided in very high specific gravity. With this general increase of the solid constituents, there is also an increase in the phosphates which may even exceed the rest of the solids; in such cases there is simultaneous increase in the sulphates.

In opposition, then, to the declaration of Lombroso, the investigations of the author show that the urine of the insane contains both absolutely and relatively less phosphorus.

But the author did observe an increase in the phosphates, both absolute and relative in some apoplectic and epileptic cases. Five cases of this kind were noted, all either in the course of general progressive paralysis or hemiplegia. After deep sleep of several hours, caused by chloral or the bromide of potash, there followed likewise a marked increase in the phosphatic excretion. But whether these differences in the excretion of phosphorus stand in any direct relation to the brain is still undecided.

The experiments made by the author on animals, finally, of which those on two rabbits and one dog are detailed, by introducing needles into the brain, or by injecting a few drops of caustic soda, prove that injuries of the brain in these animals are followed also by increase in the excretion of phosphorus.—*Schmidt's Jahrbücher*, February 23rd, 1874.

### A Case of Cystic Goitre Cured by the Drainage Tube.

By W. L. APPELY, M.D., of Cochection, New York.

Dr. L. W., æt. 65, presented himself at a meeting of the Tri-States Medical Association, March 5th 1873, with a large tumour in front of the neck, of twenty years' standing, and had not produced much inconvenience until lately it began to interfere with respiration and deglutition. He had always supposed it to be an ordinary solid enlargement of the thyroid gland. He had treated it as such; taken iodine and iodide of potassium in large doses, and for a long time, and applied iodine locally without benefit.

After an examination, the physicians present were unanimous in the opinion that the tumour was cystic. We proposed introducing the trocar and canula, but the patient declined. He allowed us to introduce the exploring needle, and we convinced him that the tumour contained a fluid. We introduced the trocar and evacuated the contents of the sac of the tumour, a brownish fluid (20 fluid ounces), and weighing 22½ ounces. He declined any further treatment at present.

May 10th he came to see me, the tumour nearly as large as at first. I introduced the trocar and emptied the sac of its contents, and injected tinct. of iodine. His general health appeared to be failing. He came to me again on the 3rd of August, much prostrated and emaciated, loss of appetite, &c.; could walk but a short distance. His friends began to apprehend a fatal result. The opening did not close entirely, and the discharge had become purulent and profuse.

I now introduced a rubber drainage tube and advised him to inject warm water twice a day. I saw him again Sept. 10th, very much improved in his general health; but a slight discharge from the tumour, which was then about the size of a hen's egg, and appeared to be the sac contracted. Saw him again Dec. 15th. He claimed to be in as good health as he ever was, and weighed as much; can walk long distances. He has left off using the tube. The opening is not entirely closed; there is a very slight discharge. He pronounces himself cured. Many of his acquaintances fail to recognise him on account of the change in the appearance of his neck.

## Medical News.

Royal College of Surgeons of England.—The following Report from the Court of Examiners of the number of Candidates who have presented themselves for the Primary and Pass Examinations for the Diploma of Member of the College during the Collegiate year 1873-74, showing the number who have passed and have been rejected from each Medical School during that period, has been issued:—

### PRIMARY EXAMINATIONS—1873-4.

Medical School.	Totals.	Number passed.	Number rejected.	Percentage of rejections.
University College	91	65	26	29.6
Guy's	90	62	28	31.1
St. Bartholomew's	63	47	16	25.4
St. Thomas's	51	38.50	12.50	24.5
St. George's	49.50	36	13.50	27.3
King's College	47	33	14	29.7
London	34	22	12	35.3
Middlesex	19	8.50	10.50	55.3

21st May, 1874.

T. B. CURLING, President.

The following were admitted members of the College on the 14th inst:—W. Gibson Bott, L.R.C.P., Kennington-park-road; C. Edward Hobbes, L.R.C.P., Bidford, Worcester-shire. The following passed the primary examination in Anatomy and Physiology on Tuesday and Wednesday last:—T. W. Brown and E. Brumwell, London Hospital; A. C. Munro, W. T. Evans, W. J. Quatrough, and A. H. Denton, Edinburgh; C. R. Naylor, Calcutta; E. G. Wool-lerton, Glasgow; W. G. H. Blake Marsh, Bristol; C. M. Anderson, J. T. Gadsby, E. G. Francis, and C. H. Cuming, University College; W. S. Burrows and J. H. Lloyd, St. George's Hospital; R. A. Newton, C. Lees, H. P. Welchman, H. Green, A. O. Holbecke, W. Pratt, J. W. O. Mogg, and R. Davies, Birmingham; W. T. Angrove, R. Bruce, and C. J. Hancock, St. Bartholomew's Hospital; F. P. Flood, Leeds; W. Thomas, W. Pilkington, G. G. Hodgson, and W. Townson, Liverpool; E. L. Freer and C. W. L. Howard, St. Mary's Hospital; R. F. Brindle and R. B.

Sellers, Manchester; G. L. Latour, Cork; J. T. Gardner and T. A. Richardson, Guy's Hospital; G. S. Badcock, J. A. Phillips, E. Sutton, and J. Potts, Charing-cross Hospital; A. Young, King's College; N. Williams, Cambridge; J. Abraham, Dublin; J. Foster, St. Thomas's Hospital.

**Queen's University in Ireland.**—The following have passed the second University examination in Medicine:—John P. Balbirnie, Robt. Beattie, David Bradley, James F. Brodie, George H. Bull, William F. Carmody, William Coates, Jephson Connell, John Coonilliac, Patrick Dempsey, Robt. Esler, Francis Meagher Geoghegan, George T. Goggin, Charles Good, James J. Gorham, H. C. Kirkpatrick, George Latour, William M'Afee, James Macnamara, Edward G. Marks, Chas. F. Marks, S. D. Martin, Robt. Moore, James Moorehead, Edmund Murphy, Channing Neill, G. F. Nicholson, Michael R. O'Connor, Wm. S. Patterson, Wm. D. Power, Wm. A. Quayle, Charles K. Tanner, Wm. H. Thornhill, John Wade, James O'B. Williams, Wm. O. Williamson, Daniel Wilson.

**Society for Relief of Widows and Orphans of Medical Men.**—The quarterly court of directors of this society was held in the rooms of the Royal Medical and Chirurgical Society July 8th, Sir George Burrows, F.R.S., president, in the chair. There were two widows added to the list of recipients of grants, thus raising the number to sixty. There was, however, a diminution in the number of children, of whom three receive assistance from the Copeland Fund. The sum divided among the applicants for the present half year was £1,279 10s. The expenses of the quarter were £107 2s., including an honorarium of 30 guineas to the secretary, in recognition of his zealous and valuable services. Six new members were elected, one under the new bye-law, by which a member may be proposed and elected at the same court.

## NOTICES TO CORRESPONDENTS.

**DR. FINCH.**—In an early number.

**FRIENDLY RIVALRY.**—The State of Illinois, America, boasts two medical colleges, and in order to place them upon a footing of equality, a full meeting of the Esculapian Society passed resolutions on the 24th ult., to the effect that jealousy and rivalry are as reprehensible in medical schools as in individuals, and that every member would discountenance and put down any attempt on the part of one school to supersede another in any other way than by genuine merit. The meeting further expressed an opinion that the two schools were equal in point of excellence.

**THE CLINIC AND THE MEDICAL PRESS.**—We are glad to find our contemporary accepts our denial that the profession in this country hates everything American. We have on more than one occasion congratulated the *Clinic* upon its smartness, and were therefore surprised and annoyed that such a charge should appear in a journal about which we had formed so favourable an opinion. However, we are glad to shake again the offered hand which does not hold the pen in vain.

We have received from Dr. Edwards Crisp a copy of a letter addressed by him to the General Medical Council in reference to the award of the Carmichael Prizes of the Council of the College of Surgeons in Ireland. Having already fully discussed the matters complained of by Dr. Crisp we cannot reopen the consideration of circumstances attending an adjudication of these prizes three years ago. Dr. Edwards Crisp, to his previous complaints (with which it is not his fault if the profession is not familiar) adds, as further grievances—Firstly, that the Council of the College did not on the last distribution of the prizes appoint the judges until some weeks after the competing essays had been sent in; secondly, that the issue of the essays in book form has been too long delayed.

On the first of these points we have to say that we are not aware that the Council of the College is bound by Mr. Carmichael's will to any particular date for the appointment of judges, and it does not appear to us to be of great importance whether they are appointed before or after the 1st of May. On the second point we agree with Dr. Crisp that an unreasonable delay has occurred, and that the essays ought to be at once given to the public.

### VACANCIES.

East London Hospital for Children. Assistant Visiting Physician. Election August 4th. Particulars may be obtained of the Secretary. (See Advt.)

Cancer Hospital, Brompton. House Surgeon and Registrar. Honorarium 75 guineas, with board and residence. Applicants must address the Chairman of the Weekly Board. (See Advt.)

## Advertisements.

**GENERAL COUNCIL OF MEDICAL EDUCATION**  
and REGISTRATION of the UNITED KINGDOM, 315 Oxford Street, London, W.—The office of the General Medical Council and of the Branch Council for England has been removed from 32 Soho Square, to the above address.  
July 9th, 1874. FRANCIS HAWKINS, M.D., Registrar.

**CANCER HOSPITAL, LONDON and BROMPTON.**—There is a Vacancy at this Hospital for a RESIDENT HOUSE-SURGEON and REGISTRAR. Candidates must be registered Members of the Royal College of Surgeons of England, and thoroughly conversant with the use of the microscope. The appointment is for one year and honorarium 75 guineas, with board and residence. Applications, with diploma and testimonials, to be addressed to the Chairman of the Weekly Board, 167 Piccadilly, on or before July 22nd, 1874.

**EAST LONDON HOSPITAL FOR CHILDREN,** RATCLIFF CROSS.—NOTICE is HEREBY GIVEN that a Vacancy has occurred in the office of ASSISTANT VISITING PHYSICIAN to this Institution. The Hospital contains 35 beds, with an average attendance of 100 out-patients daily.

Attendance is required two afternoons in the week. Further particulars may be obtained from the Secretary, at the Hospital.

Rule 6 provides that—"Every Physician eligible to this Hospital shall be either a Fellow or Member of the Royal College of Physicians of London, or a Fellow of the College of Physicians of Edinburgh or Ireland, or Graduate in Medicine of a British University, or of the Universities of Paris, Vienna, Berlin, or other University approved by the General Council of Medical Education, and be legally qualified to practise medicine in England." And Rule 8 is as follows:—"The Physicians and Surgeons in this Hospital shall not practise Pharmacy." Applications to be sent in to the Secretary, at the Hospital, on or before Thursday, the 30th instant. A Special General Court of Governors will be held for the purpose of electing such Officer on Tuesday, the 4th August, 1874, at the London Tavern, at 3.30 p.m.

THOMAS CHARRINGTON,  
Chairman of the Board of Management.  
ASHTON WARNER, Secretary.

Hospital, 8th July, 1874.

**DUBLIN INFIRMARY for DISEASES of the EYE and EAR, Ely Place.**

Consulting Surgeon:

GEORGE H. PORTER, F.R.C.S.I.; M.Ch. T.C.D. (Hon. Caus.), Surgeon in Ordinary to Her Majesty the Queen in Ireland; Fellow and Ex-President, R.C.S.I.; Senior Surgeon to the Meath Hospital.

Obstetric Physician:

JOHN CRONYN, M.D., F.R.C.S., Examiner in Midwifery, Roy. Col. Surgeons; Ex-Assistant Physician Rotunda Hospital.

Work, Income, and Expenditure for Twelve Months, ending June 30, 1873.

Annual number of Dispensary patients	...	...	...	729
Number of visits paid by such patients	...	...	...	5,847
Number of patients within the Infirmary	...	...	...	124
Number of operations performed	...	...	...	163
Total gross expenditure per bed per annum	...	...	...	£27 15 0
Average expenditure per intern patient	...	...	...	1 10 6

The Infirmary is wholly dependent on private benefactions, and is in debt to the Medical Officer. SUBSCRIPTIONS ARE EARNESTLY REQUESTED

**THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.**

PATRON:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1839, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote. Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office.

40 MOLLESWORTH STREET, DUBLIN.  
W. O'NEILL, Secretary.

Established 1848.

**PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.**

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,

&c. (KING'S COLL.), and Author of VIA MEDICA,

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

**PRACTICES AND PARTNERSHIPS NOW OPEN** for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

Y 954. LONDON, W. The SUCCESSION to a WELL-ESTABLISHED PRACTICE in the neighbourhood of the best squares, can be secured to a doubly-qualified gentleman accustomed to good society. Average receipts upwards of £1,000 a year. Midwifery, £2 2s. to £10. The dispensing is done by a chemist. One horse and brougham sufficient for the work. No assistant required. House contains fourteen rooms, and is held on beneficial lease at a rent of £150 a year. Introduction, if desired, till June, 1875.

Y 987. LONDON, S.E. An OLD-ESTABLISHED PRACTICE for TRANSFER. Ill-health has prevented the incumbent pushing the practice. Receipts, £400 a year. House contains twelve rooms, with garden, lawn, &c., at a moderate rent. The connection in the hands of an active man could be made the basis of a very extensive practice.

Y 986. In a charming locality about fifteen miles from London, a GOOD FAMILY PRACTICE which has not been pushed, the vendor having private means. Income averages £385 a year. No poor patients, and very little night work. The house contains ten rooms, with large garden, paddock, &c., beautifully situated. Rent, £40. The payment of the premium may be arranged if satisfactory security can be given.

Y 988. Near a Fashionable Spa, an EASILY WORKED FAMILY PRACTICE yielding £400 a year, and capable of great extension. Appointments, £110. Population of the district 5,000, and very little opposition, there being no other resident. The whole connection can be transferred to a suitable gentleman. Scope for at least £1,000 a year. One horse does the work. Convenient house, with garden, &c. Rent, £40. No midwifery under £1 ls. Patients chiefly middle class. Ill-health the cause of retirement.

Y 985. DEATH VACANCY in a populous manufacturing town. Receipts, £500 a year, with great scope for increase. Some excellent appointments afford a good introduction, and are believed to be easily transferable to a suitable gentleman. There is a convenient house at a low rent. Terms easy.

Y 984. PARTNERSHIP in a picturesque district of the South of England. The good income averages about £1,000 a year, but can be doubled by the co-operation of a well qualified gentleman accustomed to good society. Appointments bring in £300 a year. A Third Share is offered for transfer.

Y 983. First-class WEST-END PRACTICE with PARTNERSHIP INTRODUCTION for two or three years. The income averages £4,000 a year, but last year exceeded £5,000. Patients of the highest class. Midwifery fees from £7 7s. to £10 10s.

DR. LANGLEY'S QUARTERLY LIST of Selected Partnerships and Practices for July is now ready. Sent post free on application.

## EVANS' EXTRACT OF MALT.

This PURE Preparation of Malt, combined with the aromatic bitters, possesses in a most remarkable degree the elements admirably adapted for yielding

**NUTRITION TO PERSONS OF  
CONSTITUTIONAL DEBILITY,  
OR THOSE SUFFERING FROM LOSS OF APPETITE,  
OR FROM ENFEEBLED DIGESTION.**

Dr. Apjohn in his analysis states—"Of its constituents the most remarkable are those which include *Nitrogen*, the amount of which is unusually large—reaching as it does nearly 5 per cent. The *Proteinic* compounds in an ounce of it weigh 22.33 grains, and the analogous compounds in an ounce of beef-steak 98.48 grains. Hence, weight for weight, the *alimentary value* of the Extract is very nearly one-quarter that of the beef-steak. It is, therefore, *nutritious in a high degree, and being no doubt easy of assimilation, it must constitute an useful supplementary food in cases of debility and weak digestion.*"

Mr. Titchborne writes—"It is particularly rich in the *phosphates*, the value of which, from a *nutritive or medicinal* point of view, is becoming more palpable every day. Other preparations of this class which I have examined, on evaporation, yielded only 36 grains of Extractive to the fluid ounce, whilst yours contain 101.5 grains.

Dr. Arthur Hill Hassall (author of "Food, Water, and Air, in relation to the Public Health"; "Food and its Adulterations," &c.), London, writes—"Evans' Extract combines soothing, sedative, stimulant, tonic, and nutritive properties, which render it a most valuable remedy in cases of debility, and in many affections of the respiratory organs.

Professor Attfield, Ph.D., F.C.S., &c. (author of a "Manual of General and Pharmaceutical Chemistry," and Professor of Chemistry to the Pharmaceutical Society of Great Britain, Bloomsbury Square), London, writes—"It is a powerful restorative and gentle stimulant, and is highly nutritious in its flesh-forming, bone-forming, and general tonic characters. Evans' Extract is incomparably more valuable than any preparation of Malt hitherto offered to the public."

Prepared only by

**J. EVANS, M.D.,**

**STATE APOTHECARY AND CHEMIST**

By SPECIAL APPOINTMENT, to H.R.H. THE PRINCE OF WALES

49 DAWSON STREET, DUBLIN.

### IMPROVED AND ECONOMIC COOKERY.

#### USE LIEBIG

### COMPANY'S EXTRACT OF MEAT

as "stock" for Beef-tea, Soups, made Dishes and Sauces; gives fine flavour and great strength. Invariably adopted in households when fairly tried.

#### CAUTION:

Genuine only with Baron Liebig's facsimile across label.

### SIR WM. BURNETT'S DISINFECTING FLUID

is specially recommended  
for use by

HER MAJESTY'S PRIVY COUNCIL,  
for Deodorising and Disinfecting.  
Recommended by the Medical Profession for  
the last 25 years.

BURNETT & CO., Manufacturers,  
90 Cannon Street, E.C.

### SIR JAMES MURRAY'S ORIGINAL FLUID MAGNESIA,

THE PUREST, BEST, AND CHEAPEST PREPARATION,

HAS been prescribed for Sixty Years as the best Remedy for Acidity, Indigestion, Heartburn, Gravel, and Gout; and mixed with his Lemon Syrup, forms a pleasant effervescent Aperient, especially for Ladies and Children.

Sold by all Chemists, in Bottles, double the usual size, at 1s., 2s. 6d. and 5s. 6d. each; and in Gallon and 4-Gallon Jars for Dispensing.

HIS CORDIAL FLUID CAMPHOR

is also extensively prescribed for weak nerves, low fevers, cholera, and diarrhoea. Bottles, 1s. and 2s. each.

**AERATED LITHIA WATER.**—Messrs. BLAKE SANDFORD, and BLAKE are prepared to supply the LITHIA WATERS (of which they were the original manufacturers under Dr. Gannan's instruction) of any strength prescribed by the Profession for special cases. Those in constant use contain two grains and five grains in each bottle, either by itself or combined with BICARBONATE of POTASH or PHOSPHATE of AMMONIA. Also, POTASH, CITRATE of POTASH, SODA, SELTZER, VICHY, and MINERAL-ACID WATERS, as usual.—BLAKE, SANDFORD, and BLAKE, Pharmaceutical Chemists, 47 FLOOADILLY,

## SAINT MARY'S COLLEGE, CONWAY,

N. WALES.

Conducted by Oxford and Cambridge University Men,  
A qualified Surgeon being a  
Resident Master.

The Course of Instruction comprises the Greek, Latin, French, and German languages; Classical Composition, English Grammar and Composition, Geography, Ancient and Modern History, Writing, Arithmetic, Mapping, Book-keeping, Algebra, Mathematics, Mensuration and Land Surveying, Drawing, Natural Science, and Music. Lectures are periodically delivered by the Principal on Natural Philosophy, Chemistry, and Astronomy, accompanied by illustrations and experiments.

#### TERMS:—

£40 per Annum under 13 years.  
£50 " " over 13 " "

These Terms include the whole Course of Instruction; but brothers are received at a considerable reduction.

#### HOURS:

8 to 11, and 1.30 to 3.30. Preparations from 4 to 5.30. Dinner at 6, after which the boys go out under the care of a master for a ramble on the mountain or for a stroll on the sea shore. Pupils who are able to swim go, under the immediate care of the Head Master, for bathing at 11.15.

As a recreation, pupils are instructed (their Parents consenting) in Drilling (by a Commissioned Officer in the Army, who is also a Master in the College), Swimming, Rowing, Boxing, Fencing, Dancing, Single Stick, Gymnastics, and all the other requisites of a Gentleman's education—Riding and Driving alone being extras. There is also a Reading-room in the house, supplied with the principal daily and weekly papers, for the use of the Pupils. Great attention is paid to the morals and the manners of the Pupils. Corporal punishment is not allowed under any shape or form.

Monthly Reports of conduct and progress are sent to the Parents, and a Monthly Holiday is given by the Head Master to those Pupils only who have given satisfaction during the month.

The Michaelmas Term will begin on the 1st September; Lent Term, 1st February; and Easter Term on May 1st.

No notice is required before the removal of a Pupil, and boys may enter at any time, charge only being made for the part of the Term during which they have been present. Fee for one Term to be payable in advance—the balance in case of removal will be returned.

Applications for admission to be made to J. R. KENNEDYBELL, Esq., 9A Sackville Street, London, W.

UNDER THE SANCTION AND APPROVAL OF THE MEDICAL PROFESSION.

### WHITE'S

## SACCHARIZED HYDRATE OF MAGNESIA.

PECULIARLY ADAPTED FOR INFANTS AND CHILDREN.

THIS elegant Antacid Medicine is pure Magnesia in a fine *Gelatinous state*, which combines with the acid of the stomach, and corrects its acidity without producing any derangement. It has an alkaline and detergent property peculiar to itself, not possessed by any other fluid preparation of this Medicine. The taste is so agreeable, that children will take it with pleasure.

Sole Manufacturers and Proprietors,

### LECTURES ON BRIGHT'S DISEASE,

WITH SPECIAL REFERENCE TO

**PATHOLOGY AND TREATMENT,**

DELIVERED AT THE ROYAL INFIRMARY OF GLASGOW,

By D. CAMPBELL BLACK, M.D.,

One of the Physicians to the Hospital.

LECTURE V.

(Continued from page 531, Vol. XVII.)

PUTTING out of consideration the lardaceous degeneration of the renal arterioles, Dr. Johnson maintains that the condition to which Sir William Gull and Dr. Sutton have applied the term "arterio-capillary-fibrosis" is of artificial production, due to the effect produced on the normal *tunica adventitia* of the arterioles by immersion in glycerine and dilute acetic acid. "A sight of the preparations (of Drs. Gull and Sutton), says Dr. Johnson, convinced me at once that my surmise had been correct, and the so-called 'hyaline-fibroid' is neither more nor less than the normal *tunica adventitia*, probably hypertrophied together with the muscular coat, and certainly distended and rendered transparent by the endosmosis of the highly refracting glycerine fluid. The regular arrangement of the elongated nuclei with their long diameter in the direction of the arterial canal, and the entire absence of any abnormal appearance, afford conclusive evidence that the *tunica adventitia* has undergone no pathological change." (a) My examination of this portion of our subject compels me to affirm my unqualified adherence to the views of Dr. Johnson.

These views are substantially confirmed by the recent

(a) If the quantity of acetic acid be considerable the vessels become speedily decolorised, and the "hyaline-fibrosis" appears in a few hours.

observations of Dr. Grainger Stewart. (a) An examination of twenty-three cadavers afforded him the following conclusions. Dr. Stewart observed, besides fatty granules in vessels, aneurisms of their walls, and thrombi within them, a more or less marked thickening of the outer coat of the small arteries. This, he says, is in some cases so distinct as to attract attention by its wavy, fibrous appearance, and the sinuous outline of the vessel, where no reagent has been applied. But these appearances become much more distinct when the specimens are placed for a short time in water or in glycerine, or when a little dilute acetic acid is added. "The condition thus described corresponds exactly to the appearances of the specimens of so-called hyaline fibroid disease which I examined."

"I found in several instances distinct thickening of the middle coat, with increase of the muscular fibres. I found no evidence of atrophy of this coat. Thirdly, I found the internal coat in some parts thickened."

Dr. Stewart has found the three coats thickened in the same artery, and he failed to find in the capillaries any evidence either of thickening or of exudation on their walls.

Of Dr. Stewart's 23 cases, in 12 the blood-vessels were healthy, 5 had the middle coat thickened, 3 to a marked extent, and 2 to a slight. There were 10 in which the outer coat was thickened, and 4 in which the middle coat was also thickened. Of the 12 in which the walls were natural, there was—(1) Case of chronic peritonitis; (2) one of phthisis, with slight cirrhosis of the kidneys; (3) one of cystic disease of the kidney, fatal by uræmia; (4) one of slight cirrhosis of the liver and kidneys; (5) one of tubercle of the lungs, pleura, and peritoneum; and cerebral embolism; (6) one of typhoid fever; (7) one of pleurisy and double pneumonia, and cerebral embolism; (8) one of cirrhosis of the kidney with aneurism; (9) one of phthisis, with combined waxy and inflammatory Bright's disease; (10) one of phthisis, with inflammatory and slight waxy disease; (11) one of insolation, with slight cirrhosis of the kidney, with hypertrophy of the heart; and (12) one of waxy Bright's disease.

Of the 5 cases in which the middle coat was hyper-

(a) Brit. Med. Jour., Nov. 15th, 1873.

trophied—(1) one was a case of inflammatory Bright in the second, passing into the third stage; (2) one was another example of the same disease, fatal by hæmorrhagic apoplexy; (3) one was a case of cirrhosis of the kidney, in which the kidneys were about the normal size—in these it was well marked; (4) one of perinephritic abscess with atrophy of one kidney, and compensating hypertrophy of the other; (5) one of advanced cirrhosis of kidneys and liver.

Of the 10 cases in which the outer coat was thickened—(1) one was a case of valvular disease of the heart, with congestion of viscera; (2) one was a case of inflammatory Bright's disease, fatal in commencement of third stage—the middle coat was also thickened; (3) one was a case of acute alcoholism; (4) one was a case of carcinoma of the uterus with hydronephrosis; (5) one was a case of typhoid fever; (6) one was a case of cirrhosis of the kidney—the middle coat also was hypertrophied; (7) one was a case of perinephritic abscess—the middle coat was here also somewhat hypertrophied; (8) one was a case of inflammatory softening of the cord; (9) one was a case of commencing cirrhosis of kidneys and liver; and (10) one was a case of advanced cirrhosis of kidneys.

In 12 cases of Bright's disease the vessels were natural in 7. Of these 7, 1 was a case of waxy, 2 of waxy and inflammatory combined, and 4 of cirrhosis. Morbid conditions of vessels existed in the remaining 5 cases, of which 3 were cases of cirrhosis, and 2 of inflammatory disease. One of the last-named had the outer coat natural.

These facts seem to indicate, continues Dr. Stewart—1st. That the waxy forms of Bright's disease, and the inflammation in its early stages, have no relationship to the state of the vessels under consideration (this I have already endeavoured to explain); 2nd. That in regard to cirrhosis, although changes in the vascular walls were present in 3 cases, they were absent in 4. There seems, therefore, Dr. Stewart thinks, to be no constant relationship between the one condition and the other. Of the 10 cases in which the outer coat was thickened, there were 6 in which there was no Bright's disease whatever; but the middle coat of the arteries was hypertrophied in 5 cases, and 4 of them were cases of long-standing Bright's disease, while in the 5th one kidney was destroyed. This condition occurred in *none of the whole series that was not renal*. With respect to the relationship between the state of the vessels and hypertrophy of the heart, Dr. Stewart's cases furnish the following evidence: In 12 of the cases noted as normal, the heart was hypertrophied in 4. Of the 5 cases in which the vessels had thickened middle coats, the heart was hypertrophied in 4, and all of them were cases of Bright's disease. Of the 10 cases in which the outer coat was thickened, it was hypertrophied in 5, of which 4 were cases of Bright's disease, and 1 had valvular affection, while it was normal in 3 and small in 2. It should be stated that Dr. Stewart's experience differs from that of Dr. Johnson as to changes in the renal epithelium. He says, "I have not in these cases found changes in the epithelium, but have never failed to find increase of the connective tissue." (a)

*Analogous Changes in other Organs.*—The organs most frequently affected coetaneously with the kidneys in Bright's disease, and presenting similar pathological conditions, are the liver, the spleen, and the pancreas. In a secondary manner the intestines and the peritoneum are occasionally affected; leaving out of consideration at present the organs liable to œdema, and the diseases of the vascular system, and the cerebral disorders arising from associated apoplexy and blood-poisoning.

With respect to the *liver*, Dr. Bright found it sound in 40 cases out of 100, the change was slight in 35, and serious in 18 cases. Rayer's experience gives affection of the liver in a third of his cases, in some throughout its entire extent, in others only partially. It was enlarged

in a small proportion of cases—a sixth—and chiefly in those cases where there coexisted cardiac affection. Occasionally a portion of its peritoneal surface was adherent to the adjacent parts. In a few cases it was softer than natural, but more frequently harder, indurated, and diminished in bulk. In the latter case its surface was irregular, and of a deeper colour than usual. On section diverse morbid colours are presented. Sometimes it is pale and anæmic, its vessels containing very little blood. At other times, on the contrary, the liver presents a deep congested colour. The two conditions may co-exist in the same liver. In other cases irregular yellowish patches are apparent on the surface of the liver, interspersed with an irregular colouration of a deeper red colour than the healthy organ. These pale and red colourations prolong themselves into the interior of the organ at times. As in affections of the kidney, the liver sometimes offers a kind of exaggeration of the natural aspect of the organ. On section it appears as if granulated. This appearance seems due to a congestion of the vascular substance of the organ, by comparison with which the other portions seem paler.

As in the case of the kidney, the tissue of the liver may become the seat of fatty degeneration. The hepatic cells become loaded with fat, and the etiology is doubtless the same as in the corresponding renal affection. This condition is frequently coexistent with an increase of the interlobular connecting tissue of the hepatic parenchyma, which is an essential feature of cirrhotic degeneration; and hence Gluge and Lerboullet were led to the conclusion that cirrhosis proceeded from deposit of fat in the hepatic cells. Gluge called this particular form of cirrhosis "steatose," and described another which he believed to be due to interlobular hepatitis. In chronic cachectic nephritis fatty granulations of the liver are not unfrequent, and it cannot be doubted that they have a close affinity with the same appearances in the kidney—nay, that they are manifestations of the same constitutional diathesis. When the liver presents these granulations it is generally harder than in its normal condition.

In the true cirrhosis of the liver—the hob-nail liver of drunkards—and the analogue of the corresponding affection in the kidney, the external surface of the liver is darker in colour, crimped and irregular, and considerably diminished in size. When divided, the natural appearance is in a great measure removed, and the section presents a tuberculated surface, infiltrated with a yellowish material, grating under the scalpel; the calibre of the vessels is diminished. Furthermore, chronic atrophy of the liver presents another correspondence with the like condition in the kidney, in that the walls of the portal vein are remarkably thickened, and that in the advanced stages there is total destruction of the hepatic capillaries, and shrivelling or complete disappearance of the secreting cells. This affection of the liver causes death by the retention of bile products, just as that of the kidney does the same by retention of urinary products.

The waxy or lardaceous degeneration of the liver in like manner presents analogies to the corresponding condition of the kidney. The initial change takes place in the gland cells; the appearances are ill-defined, and easily overlooked. The first indication is that the middle portions of the lobules become reddish-yellow, translucent, and firmer than natural, and sharply defined from the surrounding dull grey rim, and hence the lobular structure is usually distinct. A solution of iodine develops glistening pellucid places everywhere of a deep red colour, the surrounding rim being only pale yellow. Ultimately the minute vessels of the liver become affected in a similar way, just as those of the kidney, their walls becoming thickened, homogeneous, and lustrous, and their channel narrowed, sometimes entirely obliterated.

As to the influence of alcohol in the production of affections of the liver, there can scarcely be said to be a difference of opinion among physicians, and Budd consequently remarks that spirits are more injurious when taken undiluted and on an empty stomach. Different views

(a) Vide Dr. Grainger Stewart's paper, *Litt. Med. Jour.*, Nov. 15th, 1873.

have been entertained as to the intimate nature of fatty liver; Andral, Thomson, Barlow, and Cruveilhier, &c., regard it as a form of atrophy. I do not regard it primarily as atrophy; the atrophy is secondary, and consequent on the degeneration of the secreting cells, as in the case of the kidney; and the opinion of Lerboullet singularly coincides with what I have advanced regarding the purposes to which fibrine is applied in the liver (*vide* pages 30 and 31), and my view of fatty degeneration in the kidney. This authority remarks: "Le développement de la graisse dans ces cellules paraît étroitement lié à un ralentissement dans le travail nutritif, et à la combustion organique, qui est la première condition de ce travail." I say this sentence accords in a remarkable manner with the phenomena of fatty degeneration, diminished temperature in uræmia, and the views of pathology advanced above.

*Affections of the Spleen and Pancreas in Cachectic Nephritis.*—In almost all instances in which the liver is affected as described, the spleen presents corresponding structural changes. Dr. Grainger Stewart has found its capsule thickened and its structure fibrous in 33·3 per cent. of cases of Bright's disease. The spleen is sometimes considerably enlarged; Rayet has seen it four times the normal volume, and full of fatty granulations similar to those which occur in the liver. In other cases where there are no granulations, the organ is friable, sometimes soft, sometimes hard and firm. In general it presents a deep colour; but on section its tissues sometimes present an appearance similar to a slice of certain sausages; at other times it is pale, exsanguine, and flabby, its texture extremely apparent, and the finger with difficulty penetrating in its structure. The spleen is sometimes the seat of tubercular matter, but this in connection with Bright's disease is a mere coincidence. Rayet has seen the spleen the seat of a large sac which communicated with the stomach.

*The Pancreas* is very seldom diseased in cases of chronic nephritis; Bright found it congested in one case, hard and firm in some, and obstructed in one case. In phthisical cases tubercular deposits have been found in it. Rayet never saw it very different from the healthy condition in nephritis. Disease of this organ has appeared in some cases in the course of pregnancy. Taking the various pathological appearances together, the etiological conditions, the anatomical and physiological similarities of the kidneys, the liver, and spleen, it cannot be doubted that their affections, in conjunction with cachectic nephritis, are not mere coincidences, but proceed from the same constitutional diathesis.

Among the diseases with which cachectic nephritis is not unfrequently coincident may be enumerated bronchitis, pneumonia, pleurisy, phthisis, psoriasis, scarlatina, syphilis, &c. The discussion of these, however, would simply be the discussion of the diseases themselves, would throw no light on the subject of cachectic nephritis, and are beyond the limits assigned to these remarks.

(To be continued.)

## MEDICAL SCIENCE AND MEDICAL TEACHING.

By GEORGE BARRACLOUGH, M.A. (Cantab.), M.R.C.S.

If, with a view to ascertain the ideas which are chiefly prevalent as to the nature and foundation of the medical sciences, we examine the opinions put forth on the subject in various lectures and addresses during the last few years, we shall find a current coming to the surface, and having a tendency to set in the direction of what is called empiricism and positivism. If, further, in regard to the doctrines ascertained to be current amongst us at the present time, we should wish to examine them, in order to gauge their value with respect to consistency, truthfulness, and probable influence on the progress and advancement of medical knowledge, it would be necessary either to examine many utterances on the subject, with a

view to ascertain their general purport and character, or to endeavour to find some one mind the expression of whose views might be deemed representative of all others of a kindred character.

I think we may justly consider that we have such a representative mind in Dr. Wilks, whose doctrines, put forth not long since in certain lectures and addresses, evoked, as the reader knows, some discussion at the time, though not so much as, from the importance of the subject, might have been anticipated. It is from a feeling that the discussion elicited at that time was inadequate and unsatisfactory that I venture what follows. It is from no love of controversy in itself, but because I consider Dr. Wilks a good representative man that I select his views as a medium for the examination of a very remarkable phase of medical opinion; and we may justly deem it a piece of good fortune that a physician of so much experience should come forward and speak boldly and at large where others had spoken in a more hesitating and less systematic manner.

Although Dr. Wilks professes the most profound horror of theory in therapeutics, yet his doctrines are abundantly theoretical, and also abundantly egotistical—faults in his, though not in my view. And what we have to examine in reference to his views are—1st, his theory of empirical therapeutics; 2nd, his theory of disease; 3rd, his theory of science; and, 4th, his theory, or "canon," as he calls it, of criticism.

Presuming that the general tenor of Dr. Wilks's views is not unknown to the reader, I may remark that the whole force of his objection to the doctrines of those who associate some theory with their practice is based on the tacit and theoretical assumption that there exists a universal and uniform experience amongst empiricists as to the value of drugs; and the individual opposition he makes to the practice of theorists is authoritative as based on this assumption. There is a *petitio principii* running through and vitiating the whole of Dr. Wilks's argument on this point. The very question in dispute, and the one which most needed proof, is assumed from the beginning. Otherwise, how could our author venture, as he does, to pronounce any drug absolutely valueless in the treatment of certain diseases, seeing that, in the absence of science, the value of any drug consists in the fact of some one believing it valuable. And there is scarcely a drug in the Pharmacopœia that someone has not believed to be of the highest value in the treatment of certain maladies, where others, by the light of their differing experiences, have come to believe the same remedy quite valueless in that class of diseases. All empirical treatment of disease is founded on faith—faith in the truthfulness of the inference drawn by the individual mind as to the share any given drug has had in promoting the recovery from disease; and there are almost as many beliefs, and these conflicting ones, as there are individual empiricists. To prove this point it would hardly be necessary to go beyond the limits of the discussion evoked by the publication of Dr. Wilks's views. Certain it is that the most cursory inspection of medical practice or medical literature makes it only too clearly manifest that the results arrived at by individual empiricists as to the value of certain drugs in the treatment of certain diseases are quite as varied and quite as contradictory as are the doctrines of theorists. I have before me a paper remarkably free from theoretical views, in which an eminent physician, as the result of his experience, records his testimony to the great value of opium, chloral hydrate, and bromide of potassium in the treatment of chorea. And these are the very remedies which Dr. Wilks, another empiricist, discredits and finds valueless in the treatment of that disease.

Writing of theoretical practitioners, Dr. Wilks affirms: "It is no doubt true that very many eminent men can give a reason for the faith that is within them; but how do they explain the success of their friends who have an equally strong contrary belief?" And, again: "As regards the propriety of administering *laxatives* in typhoid

fever, we have very contrary opinions expressed by eminent men, according to their theoretical views of the nature of the disease." Now let us put the above into a slightly different form, and see how well it applies. It is, no doubt, true that many eminent empiricists can show completely to their own satisfaction the successful results of their empirical treatment of disease; but how do they explain the successful results of their brethren, whose equally large experience has led them to adopt a wholly contrary method of treatment?

As against theorists, it was necessary for Dr. Wilks, when not falling directly back on himself, to invent the fiction, or hypothesis of a uniform experience, by which to judge of "value" in therapeutics, so as to have the appearance of confronting the varying and conflicting views of theorists with some sort of certainty and uniformity. Otherwise, there remained only the task of opposing one uncertainty with an equal uncertainty on the other side—a proceeding wholly valueless for the purpose in view. A parallel proceeding on the part of some controversial theorist would be to invent the fiction of one solely prevalent theory, contrasting this with the variety and contradictoriness of experiences, and then to have this hypothesis denied by some empiricist as ludicrously inconsistent with the real fact—viz., the existence of a vast number of conflicting theories. It does not appear to have occurred to Dr. Wilks that it was open to theorists to make this denial in respect to his own fiction. And yet it *does* seem so very natural when the learned doctor insists that "we should do far better to administer remedies in accordance with experience," to enquire, What experience? And when the reply points to the hypothetical experience it seems only natural to deny the validity of this as not in harmony with the real facts—viz., the variety and conflicting nature of actual experiences. And, again, when we are assured that particular remedies have been found valueless in particular diseases, we put the query—Found valueless by whom, or by what? And when the phantom is again pointed to as authority, the same denial naturally occurs to us. And then, after all, Dr. Wilks's hypothesis, though tacitly assumed to be self-evident, yet, as being unproved and unfounded, is only an indirect falling back upon self. For what the case really comes to is something of this sort: "I have employed certain drugs in the treatment of certain diseases, and having arrived at the belief that they are valueless in those maladies, I affirm them to be 'absolutely' of no value in such cases, because I believe this, because this is *my* belief about them." When matters, not of demonstration but of faith, are under consideration, this sort of emphatic language is only consistent where the person uttering or implying it, claims to speak as with a voice from Heaven, and this claim, accordingly, has in all ages been either virtually or actually put forward by the persons so speaking; but no such claim is conceived to be advanced in the present case. This, then, is the wrong sort of egotism, and one that cannot secure our approval. It is quite another thing to say, as might have been said, "After long and patient observation and experiment I have come to believe that certain drugs are valueless in certain diseases, and I bring forward this belief of mine, with the grounds of it, for the consideration of those engaged in the treatment of these diseases, so that they may either corroborate or correct it." This is the right sort of egotism, and one calculated to secure our approval; but, then, it would have been of no avail against theorists. The relevancy of these considerations to Dr. Wilks's views will further appear when I come to consider his canon of criticism.

Next, in what light does our author regard disease? what is his theory or conception of it? That he has some conception of it, his language would seem to imply; though what its positive characters are, it is not easy to determine. He informs us that he can show "the incorrectness of the opinion that a disease is nothing more than the totality of the symptoms." Yet this promise helps us less than we have a right to expect; for, instead of

fulfilling it in the way of showing or proving the "incorrectness," he goes off into quite other considerations; and hence we have, in place of proof, little else than the simple dogmatic affirmation of what disease is not. If, with Dr. Wilks, disease is something more than, and different from the physical symptoms or phenomena (for he uses the term indifferently) which indicate its existence, I presume we may justly infer that it is something with which we do not become acquainted through the senses, nor, indeed, through the reason, for Dr. Wilks's philosophy of knowledge, so far as he has one, does not favour the idea of any entry through this portal. As to the manner, then, of acquaintance with this disease, our only resource is to suppose that, by virtue of some intrinsic peculiarity of our author's mind, the conception arises intuitively on the contemplation of the phenomena, as the result of an instinctive belief which, so far as we are permitted to see, only enables its possessor to clothe his object with little more than the attribute of bare existence of an external or objective character. For want of a better term this sort of existence is what, in Kantian language, we must designate as noumenal. Our author evidently goes so far as to clothe his noumenon with externality and objectivity, for it is that to which he applies remedies, and urges others to do the same, it being a vain thing to apply remedies to the phenomena which only imply its existence. The most that we can add to this is that disease, as here contemplated, has a tendency or direction (though without any spatial relations), for it is spoken of as being guided in its course. This is all that we can say as to the origin of our author's conception of his very remarkable entity, if we are to take him at his word as to the methods of investigation which his philosophy rejects. Yet the real source of his theory of disease is plainly not far to seek. It manifestly has its origin in those very rational or metaphysical processes the use of which he so emphatically disavows—viz., in the processes of abstraction and generalisation from actual phenomena as perceived through the senses. But, then, the recognition of this on the part of Dr. Wilks would have involved the admission that, in order to frame a just conception of disease, it is necessary to apply to facts those very rational and theoretical processes which find no place in his philosophy. If, on rejecting the doctrine of the phenomenologists, he had paused to consider what account could be given of the source or origin of his own doctrine and knowledge of disease, he could hardly have failed to perceive how wholly misplaced was his horror of theoretical and rational processes; for he would then have seen that he was doing precisely what he censures in others—viz., theorising—adding one more variety to the theoretical views of the nature of disease. Had he halted at theorising, or doing what we all must do if we are to acquire any knowledge worthy of the name, he had not done ill; but not content with such reality as resides in physical fact, nor in scientific nor mental creations ('creatures of the fancy'—these were here the bug-bear), he must fall back on the fallacious process of misrealising his mental creations by giving them an objective and transcendental existence outside both the mind and phenomena. Thus, as a last resource, by one *salto mortale* he bounds right into the phantom land of Noumena, whither we must decline to follow him.

The real, though doubtlessly unconscious manner in which Dr. Wilks has been led to his doctrine of disease is precisely similar to that by which a certain school of metaphysicians has arrived at the doctrine of an unknowable noumenon, or "thing in itself," as external substratum of sensible qualities, and which process has been thus described by a late eminent psychologist: "What suggests the supposed substratum is merely *notionalism*, or wrong conclusions from the manner or process of our knowledge, which is the describing things by predicating qualities of them, so that in the *process* of knowledge we have to suppose the thing (for it is only temporary supposition) independent of each, and, therefore of all its qualities." What has misled Dr. Wilks is the sign of the possessive

case. Because, as a necessity of thought, we are obliged to consider disease as a unit, as a whole, though the whole is phenomenally unknown to us, so, in the use of language, we are obliged to employ such phrases as these—"phenomena of disease," "facts of disease," &c., implying by their form that disease is regarded as something more than its phenomena. Such language, of course, has its origin, in the logical or metaphysical point of view, the one, indeed, which has not been without its influence on the mind of Dr. Wilks, though he has marred it by mis-realising the metaphysical conceptions which constitute it, *i.e.*, by giving them an existence beyond both the mind and phenomena, by the same process which, as we have seen, has led philosophers to the invention of their unknowable substratum of qualities. But I shall enter into a fuller discussion of this part of the subject when science is under consideration.

Those physicians who regard the phenomena with which they are, or may come to be, acquainted, as constituting disease, point out positively to the senses as the source of their "knowledge," as they call it. And when they are censured by Dr. Wilks for supposing that this definition represents the disease or reality to which remedies are to be applied, they naturally enquire, "What sort of real entity do you offer us as a disease in opposition to our very positive physical facts? and what do you point to as the source of your knowledge, as against the very clear and positive information we give you as to the origin of our knowledge of disease? Why, you only present for our contemplation a something vaguely clothed with hyperphysical existence, which is as much beyond our powers of cognition, as it is beyond our powers of sensation. And yet to this phantom you invite us to apply genuine physical remedies, we not conceiving how such heterogeneous things can come together, but rather presuming that phantom disease requires phantom drugs, and we have none of these in our Pharmacopœia. And then, in opposition to our clear indication of the positive sources of our knowledge of disease, what do you tell us of the source of your own? Why, nothing at all of a positive nature; you simply leave us to infer the source by what—if we are to take your word for it—you have excluded. And thus we come to a "belief" which arises intuitively on the contemplation of phenomena as the source of your knowledge of disease, and which suggests the conception of a thing so vague and shadowy as wholly to escape our apprehension. For our own part, we know nothing of any such belief and conceptions in our own minds, and therefore with all deference to a mind differently constituted from ours, we cannot receive them as authorities.

Dr. Wilks urges on us the necessity of discovering the origin of disease so as to "attack" the cause. As our author's views of causation are not revealed, I will venture no remarks about the "cause," as not knowing whether he here means remote cause, or proximate cause, or efficient cause, or final cause. Perhaps he means, by cause, the first link in the chain of physical sequences, as he speaks of origin, though this is only conjecture. But what a vista opens up to us in respect to this search after origin! To accomplish what is suggested, we must—since everyone is born with his death—trace back the antecedents of actual morbid phenomena to the segmentation of the ovum. And, yet, this is going only a very little way; for this segmentation has its physical antecedents, and we have to ascend through a series of events of unknown duration to the primordial mundane egg (or however we like to conceive of origin), and to the segmentation of *that* ovum, even for those who are content with the contemplation of purely physical phenomena and the merely historical conception of cause; and for those who are not so content, but regard efficiency and finality, there is the further consideration of the first genetic conception of Ormuzd and the result of the hostile action of Ahriman on its realisation, an undertaking Titanic enough in all conscience, especially as it all has to be done without any aid from theory; and this leads us to the consideration

of our author's views of method, and of science or knowledge.

Dr. Wilks informs one of his critics that in discarding scientific methods of treatment in disease he has no intention of denouncing truly scientific methods, though he denies that, in the present state of our knowledge, we are in a position to apply even these to the treatment of disease. That the present scientific methods are not truly so, he infers from the fact that they are many and conflicting, and that no one of them is generally received by the profession. True though these latter statements may be, it is impossible to receive them as a criterion by which to judge of the scientific value of a method. That theories or methods are many and conflicting is no argument that one of them may not be true, and that no one of them is generally received at the present time has likewise no force as an objection, for we have only to recall such names as Copernicus, Kepler, and Harvey to invalidate such an argument, when we recollect how the famous doctrines associated with those names were generally rejected by contemporaries, although irrefragably true. Dr. Wilks writes as if unconscious that there exist different views of what constitutes a truly scientific method, and that these differences of view are important and fundamental. We have here, again, a manifestation of that absolutism which we found in him in reference to experience and disease. He appears to think that in uttering the mere phrase "truly scientific" he must needs possess the "thing"—the absolute entity, about which there can be no dispute as to whether it is to be received or not. This sort of proceeding has the effect of concealing the real point at issue. The persons whose methods are decried manifestly deem them as truly scientific as the nature of the case permits, otherwise they would not apply them. They might justly retort on their censor—What you affirm to be truly scientific is nothing other than what you conceive to be such—is your conception of what constitutes it; and if you frankly disclose to us what your conception is, we may or may not find something in it to adopt. Pending this disclosure we stand on our own equal rights, and prefer to follow what *we* conceive to be truly scientific. But when you shift your ground from the real point at issue, and try to confound us with insinuations about the existence of a noumenal, or an absolute scientific entity—in the way of method—binding on all by its very nature, though only existing somewhere in Phantomland, and that existence only vouched for by your own easy belief, which we can by no means receive as an authority, we must, as sane men, simply decline to entertain such doctrine for a moment.

However, let us try to get clear of this phantom business, and proceed to investigate Dr. Wilks's theory of method, and of science or knowledge. In this way, perhaps, we shall be able to arrive at a conjecture as to what his notion of a truly scientific method would be if he could relinquish his absolutism, and venture on undisguised mental conceptions like other people. But here again, we shall have to be guided to any result, rather by what is denied than by what is affirmed, the positive element being sadly deficient.

Bearing in mind the maxim of the old theologians, that *optimi corruptio est pessima*, what Dr. Wilks considers a strong argument against theory, I, and many others perhaps, consider a strong argument in its favour. "This, then," he writes, "is another argument against theory in therapeutics, that it forms the stronghold of all the false systems, that charlatanism is entirely dependent upon it." In reference to this, I may remark that even Satan himself works most mischief when he comes clothed as an angel of light, and quacks perceiving the justly high estimation in which theory has always been held by the greatest scientific authorities, are too cunning to forego the advantages of siding with the learned where the learned and the vulgar agree. It is not the mere theorising, it is the dishonesty of the quack that is to be condemned. We are further informed, in respect to

theory, that "what we want are, not the theories of individuals wrought out in their studies, but fixed principles, obtained by the ordinary scientific rules." From this it would seem to be quite a point with Dr. Wilks that theory, bad at all times, should not be wrought out in any chamber devoted to systematic thought, and thence designated a study, some particularly noxious element being conceived, I presume, to lurk in such places. Will Dr. Wilks, then, only barely tolerate theories when elaborated in the back kitchen, the street, or some open place—as a mountain-top, say; but that is so abominably cold! Would our author reject, for instance, Kepler's theory of the planetary orbits because it was elaborated in the philosopher's study, and not on the very paths of the orbits themselves? I have no wish to indulge in jesting; I am striving to find out what all this means. Does it mean simply that men ought to be painstaking in their researches, that they ought not to make abstractions hastily (*notiones temerè a rebus abstractæ* of Bacon) nor propound theories at random? If so, would it not have been as well to have said as much rather than indulge in phrases which discredit all theorising, whereas it is only some sort of theorising, or spirit of theorising which ought to be discountenanced. What beginners in science need is not to be cautioned against all theorising in the search after knowledge, but to be put on their guard against considering any provisional suppositions they may make as anything more than provisional, to be promptly rejected if found inconsistent with fresh fact. Kepler acted in this spirit when he not merely invented, but rejected nineteen theories before conceiving the twentieth, which gave the famous law of the planetary orbits.

(To be continued.)

### HYDRATE OF CHLORAL.

BY ALEXANDER G. BURNES, M.B.

THIS drug is so widely used in the present day as an hypnotic, that it may not be out of place to call attention to some of the cases in which its use is contra-indicated, the more so as several cases have been reported in which its use has been attended with serious or fatal results. The physiological action of chloral is no doubt due to its decomposition into chloroform and formic acid by the alkali of the blood, as stated by Liebreich, and chloroform being thus slowly evolved, the oxidation of the blood is lessened, as well as the evolution of carbonic acid; it is also probable, as has been recently stated, that the chloral may in the system enter into combination with albumen, and thus its decomposition may be retarded in some cases.

Bearing the above in mind, we can easily see how the use of chloral is contra-indicated in many lung affections, especially bronchitis and emphysema, where, by lessening the oxygenation of the blood, it would tend to produce lividity, or even febrile symptoms, with delirium. Dr. Sidney Ringer states that this is especially the case when emphysema and bronchitis are accompanied by obstructed circulation, in which case the effects may last several days.

Dr. Pollak (see *Medical Times and Gazette*, April 11th) also believes chloral to be unsuitable, or even dangerous, in diseases of the lungs and heart.

Chloral is likewise contra-indicated in many cases where there is heart disease, for several cases are on record where the administration of chloral has been followed by sudden faintness, weakness, and irregularity of pulse, great prostration, dyspnoea, and even death, these effects being probably due to the direct action of the chloroform on the heart, and in some states of the system the chloroform may be more quickly evolved than in others: thus, in an experiment conducted by Mr. F. J. Mavor and myself, 4 oz. of chloral dissolved in 40 oz. of water was given to a horse, and five minutes afterwards he fell down insensible, the

pulse increased from 36 to 50, but was feeble, almost imperceptible, pupils fully dilated, muscles relaxed, frequent sighing and complete anæsthesia; the temperature gradually fell from 100° to 95½°; while in another experiment the same quantity was given to the same horse dissolved in 10 oz. of water, only producing restlessness, drowsiness, purging, dilatation of pupils, and in an hour and a half, delirium, followed by slight sleep.

Chloral is likewise contra-indicated in diseases of the intestinal canal (Dr. Pollak), being liable to cause irritation and purging, especially if given in a too concentrated solution.

It is advisable not to continue with the administration of this drug for a very long period, as cases are known in which mal-nutrition of brain and nerve centres has been induced, with loss of memory and muscular strength, and in some cases imbecility and paralysis.

Lastly, chloral should be used with caution in parturition, as it may in some cases exercise a deleterious effect upon the child, as it is not so rapidly eliminated from the system as chloroform. Further research on this point is required. In conclusion, I may say, this subject is deserving of investigation, considering the reckless manner in which syrup of chloral is used by the laity as an hypnotic in all forms of disease, with, in many cases, serious results; and it is clearly the duty of the medical profession to thoroughly investigate its chemical, physiological, and therapeutic action so as to ascertain in what diseases it may be used with safety.

### REPORT ON SYPHILIS.

BY C. R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.

Senior Physician to the Metropolitan Free Hospital.

DR. FOURNIER'S LECTURES ON TERTIARY SYPHILIS.

*Complications.*—The principal complications of the gummy tumour relate either to the evolution of the gummy ulcer or to the reaction exercised by the tumour on the integuments in its neighbourhood. Let us first of all speak of those which relate to the evolution of the gummy ulcer. When the gummy ulcer is produced by the evacuation of the tumour and ulceration of the skin which covers it, it does not always tend to repair and cicatrise. Far from this, in certain cases, on the contrary, it persists if not attended to, for a long time. Thus, I have seen a patient with a terrible ulceration of the scrotum following upon a gummy tumour beneath the scrotum. This ulcer, the nature of which has remained unrecognised, dated several months back.

The gummy ulcer may progress, extend, and this far beyond its early limits, by destroying the whole thickness of the integuments, and besides putting on all the characters of a gummy ulcer which I have described above. This is the extended gummy tumour. It may even (but this is very rare) take on the phagedænic form.

In the second place, gummy tumours may create complications in their vicinity. Thus, gummata of the cranium, when unrecognised and untreated, have been known to denude the cranial bones, cause osteitis and necrosis (without mentioning the other possible accidents of these last lesions by reaction on the brain).

Dr. Mendeveille has related the fact of a gummy tumour seated near the sterno-clavicular articulation, which, unrecognised and untreated at first, caused caries of the clavicle and sternum, a caries which in its turn brought on other complications and was followed by death.

*Relapse of Gummy Tumours after being cured.*—In the last place I will point out to you a fact but little known, and absolutely-neglected by our classic writers, and yet very worthy of interest, as it seems to me. This is a sort of posthumous complication of the gummy tumour. I will explain myself. When a gummy tumour has gone through its evolution, run through all its phases and become cicatrised, it may happen—would anyone think so—that all is

not over with it. It may happen that it will be born again, as we might say, from its ashes, and reproduce itself by ulceration of the cicatrix. Of this I have already seen several examples. I have had a typical one modelled, which will explain to you better than I could do the renewed life of the gummy ulceration. Here it is:—

One of our patients, most severely attacked by syphilis, was affected, besides other accidents, with a gummy tumour of the foot. This tumour ran through its period and became cicatrised. Then, some time afterwards, the scar, although well made, and appearing to be resistant and definitive, opened at several points. New ulcers appeared, hollow, with sharply-cut edges, putri laginous base, and quite resembling those which the scar had followed.

*Diagnosis.*—Like that of all syphilitic lesions, the diagnosis of the syphilitic gummy tumour rests upon these three orders which I have spoken to you about some time ago as forming the basis of all diagnosis—the consideration of the antecedents, concomitant symptoms, and the characters peculiar to the lesion. I need not return to speak of the importance of the two first elements of diagnosis. Let us come to the proper characters of the lesion.

Does the gummy tumour present anything special or pathognomonic. As to pathognomonic, I dare not answer yes absolutely; but as to very special, I reply yes. That the gummy tumour is most specially destructive is, on the one hand a proper anatomical fact; on the other, an evolution proper to itself. The anatomical fact is the existence of the gummy slough, of this fleshy slough, white and filamentous, of which I have spoken to you already. The evolution is still more characteristic, and it is this which nosologically and clinically in my idea distinguishes best of all the gummy tumour, that is to say a tumour, primitively solid, becoming soft further on and ending in an ulcer of a rather special aspect. Solid tumour, softened tumour, and consecutive ulcer, thus is the triple phase of the gummy tumour. Well, if each of the three terms of this evolution be not special in itself, their grouping is truly characteristic of the gummy tumour.

Add to this that certain attributes of secondary character confer also on the gummy tumour a rather distinct physiognomy: the rather rounded form of the tumour, indolence at the commencement, volume usually not very large, central softening, nature of the liquor evacuated, sloughy appearance of the consecutive ulcer, stationary tendency of the ulcer, &c. There are in these various signs assuredly useful elements of diagnosis.

It is certain that a tumour which runs through three successive stages, in each of which it appears under a different form, may often and must affect resemblances and analogies of aspect with morbid states, and very different morbid states. Thus, the solid gummy tumour approaches in its symptoms all solid tumours: adenoma, cancer, fibroplastic and other tumours; the fluctuating gummy tumour has a certain analogy with cold abscess, or scrofulous abscess: the boil, sebaceous tumours of the skin when dissolving, &c.; the gummy tumour in the state of an abscess may be confounded with other syphilitic lesions of ulcerated form, with simple ulcers (notably on the lower limbs), with scrofulous ulcers, &c. But it is also certain that if, at a given moment of its evolution the gummy tumour has some resemblance with one or other of these morbid states, it differs essentially from them in its entire history and evolution.

Thus, the clinical progress of the gummy tumour (without even speaking of commemoratives) permits us pretty easily in general to distinguish this tumour from the different morbid conditions mentioned above.

I will not, then, insist in respect to differential diagnosis except upon one point, because that appears to me to have a considerable practical importance—that is, the differential diagnosis of the gummy tumour from cancer. That, gentlemen, is not a confusion invented at pleasure. This confusion has been made many times, and I have already spoken a word to you about it. Sometimes, indeed, it has ended in operations much to be regretted, of which some

examples are contained in science. The affair then merits all your attention.

On what basis are we to institute the differential diagnosis between the gummy tumour and cancer?

Four orders of considerations may serve to make this diagnosis: 1, etiological considerations; 2, differences between the symptoms proper to each lesion; 3, state of the glands; 4, influence of treatment.

1. *Etiological Considerations.*—The gummy tumour has always been preceded by accidents of specific character, and perhaps may be accompanied by actual specific accidents. There is nothing like this in cancer. Let us reserve, however, here, the possibility of morbid coincidence, for a cancer may develop itself on a subject formerly syphilitic. Cancer develops itself by preference at an advanced age, and often in subjects hereditarily predisposed; the gummy tumour on the contrary, has no favourite age.

It is useless to tell you, however, that these first considerations have only a very relative value, and that we cannot found any absolute diagnosis upon these.

Clinical considerations are of more importance, and may be summed up in the following manner:—

In *cancer* the tumour is almost always solitary; the gummy tumour is sometimes solitary, often multiple.

The *cancer* tumour may be of any size, and is generally voluminous; the gummy tumour is small, or at most, of medium size.

The *cancer* is irregular in form, ill limited, and especially with protuberances; the gummy tumour is regularly ovoid, rarely with protuberances.

The *cancer* tumour is adherent, or becomes rapidly adherent to the skin; the gummy tumour is not adherent.

Cancerous tumours are painful, stabbing pains; the gummy tumour is indolent. And note that we compare here only the gummy tumour and cancer in the crude condition. If we were to pursue this parallel to the ulcerous period, we should have to point out many other differences.

Thus, the cancerous ulcer, proceeding from the superficies to the centre, and being irregular, fungous, with soft vegetations, bleeding, fœtid, and hæmorrhagic and extensive, &c., is very different from the gummy ulcer which follows a central softening and elimination of a slough, and never presents cancer buds.

3. *Condition of the Glands.*—I have designedly separated this special sign from the other clinical elements, hoping thus better to express its great importance.

In *cancer* the glands are very rapidly affected; in the gummy tumour the glands are intact.

This is an excellent sign, which, with very few exceptions, suffices (at any rate at a certain period) to distinguish cancer from gummy tumours.

4. *Treatment.*—There is no action on cancer by iodine or mercury. On the gummy tumour the resolutive action of these remedies is rapid, with very rare exceptions. Treatment here serves as a *touchstone*, as they say, so rapid is its action. It is therefore an absolute rule of practice, in the conditions where the diagnosis of cancer and gummy tumour may offer some difficulty, never to operate before having tried iodide of potassium. In fact, if we open the journals, we shall find numbers of observations similar to the following: A tumour presents, it is said, all the signs of cancer; to free the conscience, iodide of potassium is given, and the practitioner is stupified by observing this cancer resolve, melt away, and become absorbed. The pretended cancer was only a gummy tumour. I have myself seen several cases of the kind.

*Prognosis.*—Gummata of the cellular tissue have in general no direct gravity: there is more or less prolonged suppuration, with destruction of the skin to a greater or less extent, persistent scars; that is in sum the evil they cause. They are not truly serious, as far as lesions, save in a relatively small number of cases, and rather rarely. But gummy tumours are especially grave on account of the conditions they indicate: they testify to tertiary syphilis; they show that syphilis is entered into that period where serious lesions may appear.

In this point, again, there is a distinction worth making. An isolated gummy tumour—even two or three such tumours have the same prognostic signification as any other tertiary accident: they testify to the tertiary condition, that is all; they do not announce a specially grave form of syphilis.

Multiple gummy tumours, on the contrary, coming on simultaneously, or succeeding at short intervals, have an extremely grave signification: they testify to syphilis of malignant nature; they point to a profound infection, an unfortunate tendency of the diathesis towards morbid products multiple and dangerous, and to a grave reaction on the general health. When you see multiple gummy tumours on a patient, be warned that you are about to have rude attacks to support.

Everything is to be dreaded in such like cases; and the proof of this that multiple gummy tumours figure habitually and in the first rank in the *cortège* of the accidents which accompany syphilitic cachexia.

If now we make the influence of treatment intervene in the balance of the prognosis, we arrive at this result: Isolated gummy tumours (or at any rate non-multiple) in general undergo most marked curative influence from specific treatment. They are cured by the iodide of potassium. It is a miracle even to see how easily the iodide absorbs them. Multiple gummy tumours, on the contrary, are infinitely more obstinate: often they get well at one point only to arise in another: sometimes even they resist entirely.

*Treatment.*—Before saying what it is right to do against the lesions we are speaking of, let us commence to say what we ought not to do.

1. What we ought not to do (and history is before us to show whether these negative precepts are superfluous) is first to remove gummy tumours, or operate on them by any process whatever, were it the most perfect in the world. First of all the operation is painful, and may also be dangerous. Besides, it is a perfectly useless operation, for the iodide can replace the knife, and the knife itself would not be certain to cure. Gummy tumours, indeed, have been known to return after removal.

2. What again should not be done, is to attack gummy tumours with caustics, in order to open them or to destroy them. This is another operation quite as useless as the preceding for the same reasons.

3. What we must abstain from again is to open gummy tumours, even when fluctuating, as fluctuating as possible. And why? Because the resolution of a gummy tumour is always possible, at all its periods, even in the period of softening, even when the tumour is fluctuating. Examples abound in which gummy tumours have been seen to fluctuate, and on the point of opening, and yet diminish and be reabsorbed under the influence of the iodide.

We must, then, forbid any meddling with a gummy tumour, or opening of it, at any time whatsoever. This is the rule.

It is of course useless to add that this rule is not so absolute that it must be obeyed in all cases and without exceptions. Evidently, if special indications arise, or a gummy tumour is so advanced in its development that resolution is not to be hoped for, if by its presence it cause a considerable oppression or become the occasion of functional disturbance, the special indication here dominates the general rule, and we ought to satisfy it.

These negative precepts being laid down, let us see, in the second place, what we ought to do. What we ought to do is very simple: administer the iodide of potassium at once, in sufficient doses (1, 2, 3 grammes = 15, 30, 45 grains), according to the tolerance of the remedy, and in doses which must be stronger and more rapidly progressive as the development of the gummy tumour is more advanced. In such a case, I repeat, the iodide of potassium possesses a surprising activity in doing what no remedy can do for any other tumour, in absorbing it. It resolves and absorbs the gummy tumours with astonishing activity and rapidity. It resolves even the largest gummata.

It is always the iodide of potassium we ought to prescribe

at first; alone, in fact, it suffices most frequently for the cure. It is rather rare that we are forced to associate mercury with it.

The indication of calling in the aid of mercury to that of the iodide of potassium scarcely presents itself, except in two classes of cases. 1st. In precocious gummy tumours, when the disease is still young, at the time when the mercury is most active. 2nd. Against rebellious gummy tumours.

And it is also in these two orders of cases that it is fitting to put into action, along with specifics, the different agents of analeptic medication; for in these two orders of cases the production of gummy tumours is most frequently connected with a certain amount of impoverishment of the organism, with a bad general condition, whether anterior and foreign to the diathesis, or engendered by it.

Lastly, one word as to the local treatment of gummy tumours.

In the first and second periods treatment plays only a secondary part. Some have proposed, and often employ at this epoch, as adjuvants of the treatment, certain local means—friction of mercury and iodine, or with the tincture of iodine, blisters placed on the tumour, &c. It is difficult to gain any precise opinion as to the amount of action of these different remedies, for they have never been employed alone. What alone we can say of them is that they are not injurious, and that they appear to enjoy a certain degree of efficacy as resolutive.

But as soon as the gummy tumour is opened, local treatment is far the most urgent.

First of all, when the gummy tumour is being eliminated, some hygienic remedies are indispensable, baths and emollient poultices in order to moderate the peripheral congestion, with detersive lotions injected into the interior of the gummy cavity. Lastly, when the gummy tumour is laid open it is necessary to dress it. Practitioners have vaunted many ointments, and many solutions and topical applications for this purpose. I believe that none are so useful as the covering up the part with Vigo's plaster, a mode of dressing concerning which I shall have to speak at length apropos of tertiary syphilitic eruptions, and which in this case, as in these, succeeds admirably as a general rule. The gummy ulcer is, after all, only a tertiary skin disease; it should then be treated as such, and I postpone what I shall have to say to you to our next meeting, when I shall speak to you in detail concerning that kind of accident.

But when the gummy tumour is cured the task of the practitioner is not yet finished. We must remember that the gummy tumour attests a tertiary state ready to re-enter the stage, to be born again *in situ*, or to engender elsewhere accidents of another kind. The duty, then, of the practitioner is still to watch the patient, to warn him of the dangers he may encounter, and to ward these off by continuing the treatment of the diathesis for a long time after the local cure.

In another lecture, edited by Dr. Porak (*France Médicale*, June 3), Dr. A. Fournier speaks of the elements of diagnosis in tertiary syphilis, which may be derived from the three following sources:—

1st. *The proper characteristic of the lesion.*

2nd. *Co-existence of specific accidents.*—When account is taken of the possibility of coincidences, this is a very important element in diagnosis. As example of this, Dr. Fournier cites the following fact: A patient entered hospital with all the symptoms of a cavity in the lungs; at the first glance the diagnosis was made of tubercular phthisis; but on the following day, when the patient was more nearly inspected, there was noticed to be an exostosis on his body. This was a ray of light. M. Gubler, the able physician from whom this case was borrowed, suspected syphilitic phthisis, and gave iodide of potassium. Some weeks later, this patient, at first considered tuberculous, that is condemned to death, quitted the hospital perfectly cured.

3rd. *Specific antecedents.*—When based on these three considerations the diagnosis is at once sure and easy; but

it is rare that these are all found present in practice; the diagnosis then becomes very difficult and thorny, and we then obtain for the most part only the elements of probability.

Besides the difficulties inherent in all diagnosis, we meet with some special to tertiary syphilis. It is the latter class especially which ought first of all to arrest us; each of the three elements of diagnosis above alluded to may be wanting; and they may even all of them be wanting together, thus—

1st. There are few tertiary syphilitic lesions which present a pathognomonic symptomatology. The lesion we have to recognise has usually no special character.

2nd. Most frequently the tertiary syphilitic lesion is solitary, and we are unaided in the diagnosis by any other actual syphilitic manifestation.

3rd. The antecedents are most commonly wanting, especially in women. In that sex they are wanting on an average once in 4 or 5 cases, and they are wanting because they may be forgotten, misunderstood, or dissimulated.

In the diagnosis of tertiary syphilis we have to beware of two rocks—

1st. The very distant epoch at which tertiary syphilis may appear is of itself a cause of error and surprise.

2nd. The influence of the surrounding circumstances. There are certain conditions and certain surroundings where the physician forgets syphilis, where he no longer thinks of it, where he would not even dare to suspect it. The moral situation of the patient, his character, his social position concur more than once to confirm the practitioner.

*Prognosis and Treatment.*—The question of prognosis is closely mixed up with that of treatment. In a general way, we may say that tertiary syphilis is always serious, often grave, sometimes, and more frequently than is supposed, mortal. It is useless to add that the conditions of prognosis vary according to multiple elements, some connected with the lesion (its seat, extent, period, &c.), others on the condition of the patient. But what modifies most certainly our prognosis is assuredly treatment—"syphilis discovered, they say, is syphilis half cured." If this be true for syphilis in general, it is still more true for tertiary syphilis in particular, which is essentially under the influence of therapeutics, and obeys even better so-called specific agents than primary or secondary syphilis does.

Iodide of potassium is the remedy *par excellence* of tertiary syphilis. It enjoys such curative efficacy in the majority of cases that, without sinning from excess of enthusiasm, we may qualify it as a marvellous and incomparable remedy.

Yet we must not the less remember that iodide of potassium, even aided by mercury, is not all-powerful and infallible against tertiary syphilis. Truly, it cures in the majority of cases, but it does not always cure. Like all remedies, it has its weaknesses, its unsuccessful cases, its reverses. For one or other reason, tertiary syphilis is but too often obstinate to treatment, whether the remedies have intervened too late, or that around the syphilitic lesions there have been produced lesions of ordinary nature, such, for example, as in the case of syphilis of the brain. Round a gummy tumour, or near a caries, common encephalitis is produced: the iodide cures the gummy tumour or the caries but is inert against the encephalitis. Lastly, we ought to know that certain cases are, from their nature, beyond the powers of art.

Such are the cases where incessant relapses follow repeated cures, where we are always curing without ever curing; such are especially these cases, so grave, where syphilis at once has an evolution which we cannot better name than to call it desperate, accumulating accident upon accident, deriding all the efforts of therapeutics, and showing itself stronger than all remedies.

In general, adds M. Fournier, people are not sufficiently afraid of syphilis. To listen to some practitioners, all that is syphilitic ought to be cured because it is syphilitic. This is not always true, and those who see syphilis close to them learn to fear it more. Hence the practical conclusion: As syphilis exposes patients in the distant future to grave

dangers, it is important to combat it in its infancy to set aside the future possibility of such accidents.

To prevent is still easier than to cure, as far as syphilis is concerned; so that all is in the treatment constituted as soon as the diathesis begins. In presence of a case of early or recent syphilis, the result which the practitioner ought to seek to obtain is to set aside the far-off possibility of tertiary syphilis. The ideal he should pursue is to alleviate the diathesis in the present to make the future safe, and it is for this end that he ought at once to attack syphilis by a treatment at once immediate, energetic, and prolonged.

## ON INCONTINENCE OF URINE IN CHILDREN. (a)

By HENRY KENNEDY, F.K.Q.C.P.,

Ex-Physician to Cork Street Fever Hospital, Dublin.

DR. KENNEDY began by observing that though the affection could not, in one sense, be considered serious, it, at any rate, always entailed a great deal of annoyance, and was ever most difficult of cure, and in some rare cases it continued on even into adult life, so rendering the individual miserable. In many cases too, boys had to be taken from school on account of it, and this made it a very serious infirmity, for very obvious reasons. The author did not bring forward the subject with the hope of offering anything new, but in order to elicit discussion. Before alluding to the affection itself, he wished to draw the attention of the meeting to the marked differences to be observed amongst children at and after birth, and these differences went on even into childhood. They were seen in the external parts of the body, and also in the internal functions. Some had very sensitive stomach and bowels, others the contrary; some swallowed badly; some had their teeth very early, and others late; some walked much sooner than others; and when they were old enough the variety in the modes and powers of speech was very striking. It was known to all, too, that girls spoke earlier than boys, and that stammering was much more common amongst males than females. Now, all these differences, the author went on to observe, must arise from some inherent cause, and when they amounted to what would be called a defect, it was most probable they arose from some want of harmony in the functions of the nervous system. When a child was born with one side of the body weak, or atrophied, it was known that this was due to a want of development, or even an absence of some portion of the nervous centres. So the author took it to be—though in a very much mitigated form—in the affection of which he was about to speak. It was certain it could not be due to any abiding cause, inasmuch as all children, it might be said, grew out of it. But the author considered that the affection was as close to real disease as it could well be without being it. He drew attention to the fact, that while the incontinence of urine was a comparatively frequent affection, the bowel was not affected with it. Still, this did occasionally occur, and he had met instances of it. He also noticed the variety that exists, even amongst adults, as regards the performance of the functions of the bladder; and hence he concluded that if such were known to exist amongst them it might *a priori* be supposed to exist amongst children, where the several functions could not be supposed to have attained their maturity. The author went on to state that the affection was probably more frequent amongst boys than girls. But this point required further confirmation. In one remarkable case of which he knew, the infirmity had continued up to womanhood, and then the patient married, though under such peculiar circumstances. The effect, however, was that from that moment she was cured. It was worth keeping in mind that the affection was not confined to the night, at least, in some instances; there were exceptions, and he had seen one very recently. The boy was 10 years of age, and small for his years. This case was unfortunately lost sight of. A case of this kind was of course more serious than where the affection was confined to the night. As to the infirmity itself, the author said it required no description. The child wet the bed once, or it might be, as often

(a) Abstract of a paper read before the Dublin Obstetrical Society.

as three times in the same night, and this, as all knew, constituted the complaint. There was a feature about it, however, that was worthy of notice in connection with its natural history, and that was, that it frequently intermitted—that is, the affection would suddenly cease for a period, and then return, or it would lessen in intensity for a time. When the question of treatment was discussed this point was not to be forgotten, for that might be set down to treatment, which, in reality was but a feature in the affection itself. The treatment was divided into the mechanical and medical. Amongst the former was included the plan of Sir Dominic Corrigan, which the author thought could scarcely be successful, and might possibly lead to the prepuce itself being turned into a receptacle for the urine, and in confirmation of this he mentioned a case the particulars of which the late Sir Philip Crampton had told him, where the tying a thread round the prepuce for the purpose of keeping in the urine had led to the formation of a new bladder. If any plan of this kind were now tried the author observed that the pressure should be applied at the root of the penis, and further, it would be much easier of application now-a-days than formerly, inasmuch as vulcanised india-rubber could be used, a ring of which would probably answer the purpose well. It was evident, too, that it would require medical supervision, but could of course be only applicable to boys. A very old plan, with the same object in view, was the strapping on a bit of bougie, so as to compress the urethra. In one case where the author tried this plan it had failed; and like the last plan it also required close watching and attention. Of the medical means employed, blisters to the sacrum must not be forgotten. There could be no doubt, the author said, this means had succeeded. Of two cases in which he had employed it, it failed in the first; but in the second it was more successful, and stopped the infirmity for four months. The patient was at this time a girl of 8 years of age, and the mother was advised to wait till she became a woman, and she was told the infirmity would cease. Strange to say, this girl was brought to the author by her mother this past week; but though menstruation has been established, the infirmity is as bad as ever. She is now 15 years of age. Whether she will be cured remains to be seen. The regulation of the quantity of fluids taken, and the time, the author considered of much moment; and he particularly advised against the use of tea. There was one measure, too, he thought of the greatest consequence, and that was the teaching the patient, when such was possible, the habit of retaining the water as long as possible in the day time. By this means the sensibility of the bladder was lessened, and good was effected. The author observed that this plan was opposed to the one of taking up the child at night, which, though it diminishes the unpleasant effects of the infirmity, had no tendency to cure the complaint, but, as he thought, the very contrary. To two medicines only did the author allude, hydrate of chloral being one, and belladonna the other. There was already some evidence that the former had been of service, but it was not sufficient yet to establish its value. The latter, as a whole, had proved the most valuable drug yet used, and had cured a good many cases. Of two cases in which the author gave it it cured the first, a boy of 3½ years of age. In the second, a boy of 11, it has bettered him a good deal; but circumstances had prevented as full a trial of the drug as was desirable. In speaking of belladonna, the author adverted to the remarkable fact that children bore it in very much larger doses than adults. By gradually increasing the dose he had given it in very large quantities. It had rarely dilated the pupils, and then only for a short period. In prescribing it this point was not to be forgotten. There could be little doubt that the internal organs, especially the kidneys, were so active in childhood that the poison was very rapidly eliminated from the system.

## Hospital Reports.

### METROPOLITAN FREE HOSPITAL.

(Cases under the care of Dr. C. R. DRYSDALE.)

#### *Albuminuria Syphilitica.*

THOMAS AUSTIN, æt. 40, dock labourer, admitted into Prince's Ward 2, May 15th, 1874. States that three months ago first noticed his feet and legs began to

swell, and sometimes his face. Has only been able to do five days' work in three months. Has been much exposed to wet weather at his work; has been a moderate drinker; had syphilis twelve years ago; there are some scars on thighs. About nine months ago had a similar attack, and was ill for some weeks; is a big-built man, and looks pretty healthy; tongue clean; bowels open; passes but little water; pulse 76; the legs are swollen and oedematous; the abdomen is pretty tense, but nothing abnormal is felt; heart and lungs appear natural; urine is pale, acid, sp. gr. 1005, contains a very considerable quantity of albumen; takes food pretty well; says he has attended at this hospital off and on for four years for pains and lumps in his head, which were always worse at night. Soon got relief, and was well for a time.

To take M. Sal. lax., ʒj., t. d. Half diet.

26th.—Urine much the same; swelling no less; to have pot. bitart., ʒss.; pot. nit., gr. x.; pot. acet., gr. xx.; aq. ad ʒi., t. d. Pulv. scam. co., gr. x., p. r. n.

June 1st.—Bowels are freely open after medicine; swelling is less; prognosis bad.

8th.—Swelling of legs has much diminished, but urine still contains much albumen. Is now complaining of his head again, for which he is to take—M. Pot. iod. alk. ʒj. t. d.

9th.—Discharged. To be an out-patient.

#### *Hereditary Syphilitic Laryngitis.*

Stephen Carie, æt. 11 years, was brought to hospital on May 1st, 1874, by his mother, for great difficulty in breathing. The mother states that he first experienced difficulty in breathing some little time before last Christmas, when he was taken to the London Hospital, where, after he had been an in-patient for some time, tracheotomy was performed, and the tube was kept in some weeks, after which he was discharged much relieved; but the last few weeks he has become so much worse, especially at night, that the mother became alarmed lest he should be suffocated.

On examination of throat, irregular ulcers were found at the root of tongue and around fauces; he expectorates a large quantity of thick mucus. General health is pretty good, but he is rather thin.

The laryngoscope shows narrowing of the glottis and marks of old ulceration about the epiglottis.

Air appears to enter lungs in all parts; but there is a loud whistling sound over trachea and larynx during respirations. To take—M. Pot. iod. alk. ʒj. t. d. (gr. x.).

Mother is a strong, big, fat, healthy-looking woman. Has had twelve children, seven of whom died young—she says of fevers, &c. No history of syphilis can be made out, but she answered all questions in a most careless and indifferent manner.

Remained in hospital under same treatment till June 10th, when he was discharged much relieved and in better health.

This is the second case of hereditary affection of the larynx that has been under Dr. Drysdale's care in this hospital.

#### *Alopecia Areata, or Tinea Decalvans.*

Peter Carroll, æt. 8, came to the Metropolitan Free Hospital on the 27th February, 1874, suffering from almost perfect baldness of the head. According to the woman who takes care of the boy, the disease commenced about six months ago, before he had measles. He was in good health at the time. He attended at that time a little school in his neighbourhood, in Blackwall. The disease commenced with small patches over the whole of the head; but he had never been taken for any medical aid before he came to the Metropolitan Free Hospital. There was almost literally not a single hair left, the only exception to this being in a small patch the size of a shilling over the right frontal bone. On some parts of the scalp the skin is smooth, and without any appearance of even "lanugo;" on others there is a little down. The

pigmentum iodi was used on parts of the scalp at a time, and he had ol. menth. ʒij., vin. ferri ʒj., to take thrice daily. The prognosis was very bad; but Dr. Drysdale intended to keep up blistering the scalp with blistering fluid for some months. His idea is that this disease is like tinea tonsurans, caused by a parasite, and he dissents from the view taken of it by E. Wilson and his scholars.

#### *Epilepsy from Tickling.*

Sophia Beal, æt. 22, seven years ago was tickled by a man beneath the arms, and had a fit in consequence. Has had often two or three fits in the week; is quite insensible; has a peculiar feeling in the leg before the fits come on. She is regular sometimes for two or three months together. Has had more fits (she thinks) since marriage than before. Never been more than three weeks without a fit. They are worse in warm weather. Has had no children.

*Remark.*—It is very notable among the great mass of cases of epilepsy which attend at the Metropolitan Free Hospital in the course of a year how many of them have been brought on by causes similar to that here assigned by the patient. Fright, violent anger, tickling, and great sorrow have in numerous instances served as the antecedents of the first fit.

### CASHEL UNION HOSPITAL.

(Under the care of DR. LAFFAN.)

#### *Bloodless Operating.*

THE invention of the distinguished surgeon of Keil has excited sufficient interest in the profession to invite the publication of occasional notes on its practical working.

The appliance of Esmarch is very simple. It consists of a roll of elastic webbing of sufficient length to bandage any limb to which it may be desired to apply it; and of a hollow elastic tube furnished with catches at the extremities. The webbing is applied evenly and tightly to the limb, and then the elastic ring is wound tightly round it at the outer border of the webbing. The latter is then removed, and the band held in position by an assistant, or fastened with such care as to dispense with any such assistance. The webbing is designed to empty all the superficial vessels of their contents, while the elastic band forbids the entrance of fresh supplies. In this way the part is rendered "bloodless" for the time.

I recently admitted to my wards a patient to whose condition this contrivance seemed specially applicable. It was that of an anæmic old man, who was suffering from epithelioma of the heel of some months' standing. Having determined to operate, I previously applied the apparatus in the way described. The band was maintained in position by my dresser, Mr. James Dwyer, while I proceeded to excise the diseased mass. This was effected easily, and without the loss of a single drop of blood. The clear view that was afforded of the parts by the entire absence of all blood-flow strongly contrasted with what would have obtained under the usual method. The operation completed, some little oozing had to be permitted in order to allow of my seeing the vessels which required to be secured. In this case the amount of blood saved was of the utmost consequence to the patient. No sloughing ensued, although the low state of vitality of the limb, seamed as it happened to be with the cicatrices of old ulcers, was particularly favourable to such a process.

Mr. Bryant has drawn a very apposite distinction between Esmarch's procedure and that of removal of growths, &c., by the *écraseur* or by the galvanic knife by denominating the application of the one "bloodless operating," and that of the other "bloodless operations." The after-oozing on which this distinction has been founded, and which is necessary for the tying of the vessels, is the one imperfection of this appliance. As regards its possible

dangers, surgeons have feared that it would lead to sloughing, or produce thrombic disturbances, and one or two cases of the former have been reported. Now, sloughing has happened where no such appliance was used, and there was, moreover, wanting in the cases reported that fulness of proof necessary to establish the connection of cause and effect between the two; and even allowing the existence of such a connection, one or two instances of sloughing is a very small percentage out of the multitude of cases in which the apparatus has now been used.

The dependence of sloughing on its use and the estimation of the other possible dangers apprehended from it remain yet to be worked out; meanwhile, as an economiser of the vital fluid, Esmarch's procedure promises to be of such value as to merit yet more extensive trials.

## Transactions of Societies.

### DUBLIN OBSTETRICAL SOCIETY.

At the meeting on June 13th, Dr. LOMBE ATTHILL in the chair,

Dr. HENRY KENNEDY read a paper on

#### INCONTINENCE OF URINE IN CHILDREN,

which will be found at page 89.

In the debate which followed the reading of the communication,

Dr. DARBY said he quite agreed with Dr. Kennedy that the disease was mostly confined to boys, and the complaint generally determined at the age of puberty. He knew an instance in which the disease was transmitted through three generations. The treatment recommended by Sir Dominic Corrigan had been most successful, and in every case it remedied the affection in a very short time—in the course of a week in one case, a month in another, two or three months in a third—but in all the cases perfectly successfully. There was one remedy to which Dr. Kennedy had not alluded, and that was the tincture of cantharides. He knew of an instance in which a boy, suffering from the disease, was taking cantharides for the whooping-cough, with which he was also troubled, and he was cured of the incontinence of urine as well as the cough.

Dr. C. F. MOORE mentioned a case in which a lady had been recommended to give her child belladonna in order to keep away scarlatina. In consequence, she gave her son belladonna very largely, and continued it for a considerable time. The result was that the child permanently and entirely lost his sight. Dr. Moore said he thought it well to mention that circumstance because some of their junior members might be under the impression that there was no harm in belladonna.

Dr. CHURCHILL sen. said that the disease was a most obstinate one. In some cases he thought it happened from acidity of the urine. He had seen benefit result from the use of belladonna, although he never gave it in very large doses. He had also seen good effects follow the use of the cold douche before bed-time, but he believed the best treatment was careful watching. He thought there was a remarkable difference between the day and the night. He had taken some trouble to ascertain what time in the night it was that the complaint prevailed—whether it was when the child was in a sound sleep or in that half-sleep which preceded waking, and in some cases he found that it occurred during deep sleep. In others he found that it occurred in a half-sleep, and it was quite clear that in others it had taken place during dreams about passing water. He was not quite sure also whether some of those cases might not occur from want of proper tone in the bladder, which might be remedied by some styptic. He would not be inclined to adopt mechanical pressure. He considered the disease a very difficult one to cure.

Dr. KIDD said that so far as his experience went, he thought that one of the methods alluded to by Dr. Kennedy was most efficacious, and he thought it a most relational method of treating this disease. It was one that he (Dr. Kidd) had in every case that came under his notice recommended and impressed upon the parents, and upon the patients themselves, where the latter were of an impressible age—that was, the importance of educating the bladder during the day-time to retain the water. He believed, so far as his experience went,

that that was the best mode of treatment. Teach the patients to retain water as long during the day as possible: in that way they would accustom the bladder to the retention of the water, and in very many cases he believed they would prevent the irritability of the organ which caused the incontinence. In another point that Dr. Kennedy had alluded to, he (Dr. Kidd) did not so fully agree with him, and that was with reference to abstinence from fluids. He thought if they made children abstain from drinking fluids it rendered the urine more irritating, and, so far as his scanty observation had enabled him to form an opinion, they rather increased the tendency to wet the bed. There was another point to which he desired to refer. Sometimes incontinence was the result of epilepsy. In many cases of epilepsy where fits occurred at night the fact of their having happened was only known by the bed being wet. They all knew that epileptic patients had their fits only during sleep, and if those patients slept in rooms by themselves, it was, in fact, not known where the fits took place, except by the state of the beds. In cases where he had had reason to suspect epilepsy he had found that the patients had wet their beds. In considering the question the connection of the disease under discussion with epilepsy was a point which deserved to be borne in mind. With regard to the treatment of such cases, and as to the best bed for a patient of that kind, he might mention that early in his life he had occasion to watch very closely a case of this sort. The patient was the son of a medical man, and was a very clever athlete. He, however, up to the age of puberty suffered from incontinence of urine, and his father resorted to many devices to keep the bedding in a wholesome condition. Amongst other appliances, india-rubber sheeting was used, and of all the devices that could be imagined, he (the speaker) considered that the worst, because the child would lie all night in a pool of urine, the skin being irritated, and the child constantly getting cold. Similar sheeting with tubes in it to let off the water was in use at Lucan, and the best of that kind was he thought Hooper's square sheet of india-rubber with a tube in the centre which carried off the water into a pan placed under the bed. He was of opinion, however, that by far the best bed for patients suffering from the disease was that made up of pure clean wheat straw. At an asylum in Sligo the dirty patients lay upon stretchers, each composed of a sheet of some peculiar canvas stretched on two poles, covered by blankets folded in the way described by Sir Dominic Corrigan in his "Lectures on Fever." He (Dr. Kidd) was told that that method was even better than straw. He thought the tincture of the muriate of iron deserved more credit than it had received.

Dr. LOMBE ATTHILL (the Chairman) said that there was no doubt that some children wet the bed while in the act of waking, and others did so while in a profound sleep. He had seen that day an exceedingly fine handsome girl of 18 years of age who is affected with incontinence of urine. The remarkable feature in her case was that when on a visit with a friend, and not at home, she never wets the bed unless the visit be prolonged to seven or eight days. The only explanation he could give of that was, that when in strange places her sleep was not so deep as when at home. She now always wets the bed at the menstrual period. He had not the amount of success with Sir Dominic Corrigan's remedy which Dr. Darby had had. Great care must be taken in applying the collodion, and if that were done, and the proper precautions taken, he was not prepared to say that the treatment was fallacious. He was, therefore, not at liberty to condemn it. Some time ago he (Dr. Atthill) saw a boy with the troublesome complaint, and the remarkable circumstance in his case was, that when taken out of bed at night, if the weather were in the least cold, he could not pass one drop of water. When, however, that child was replaced in bed, in fifteen minutes he would pass water. With Dr. Churchill he (Dr. Atthill) thought a cold spine-bath would be of service, and he was also of opinion that straw suited admirably for the beds of patients suffering from this disease.

Dr. T. MORE MADDEN said that in the present number of the *Irish Hospital Gazette* he had published some cases of this disease. In the Children's Hospital a good many cases of the kind had come before them, and as the complaint was not only very common, but also occasionally a very difficult one to cure, he was sure that the society must feel much indebted to Dr. Henry Kennedy for the very valuable and instructive paper he had just read on a subject of such practical interest. The cases of incontinence of urine during sleep, or infantile enuresis,

which had come under his care in that and other institutions for children, in some instances resulted from reflex spinal irritation, or from irritability of the bladder, or from calculus, or from impaired contractility of the sphincter vesicle, or from an abnormally acrid condition of the urine acting on a morbid state of the neck of the bladder, but far more commonly he believed that it was not a disease, but a habit, and therefore preventible, being the result of neglect and carelessness on the part of the nurse in not taking the child up at proper intervals to pass water, and in these cases it obviously required moral and preventive rather than medical treatment. He remembered some years ago hearing a discussion on Sir Dominic Corrigan's excellent paper on this subject, in the course of which Dr. Darby said that in the Loughlinstown Hospital he was able in the great majority of cases to prevent this habit by punishing the nurse who had charge of the patient, and in the course of his own experience he (Dr. More Madden) had found this vicariously applied preventive treatment very effectual in several instances in which the complaint was merely the result of habit or neglect. But when it resulted from any diseased condition, such as he had already referred to, incontinence of urine could only be cured by removing its exciting cause; and they could not be too careful in not allowing, as was too often the case, a child to be punished for what its parents or nurse considered a mere dirty habit, but which might be really the result of disease. Amongst the cases of enuresis at present under Dr. More Madden's care was one illustrating the difficulty of curing this disease in some instances, and the necessity of studying its causes in each case. In the case he referred to the patient, who had nearly arrived at adult life, was still suffering from this most unpleasant affection, by which his life was rendered perfectly wretched, and having been repeatedly punished for it when a schoolboy, had been since ashamed to apply for medical treatment, under which there seemed every prospect of his being speedily cured. Speaking of the medical treatment, he entirely agreed with Dr. Henry Kennedy that blistering the sacrum was one of the most effectual remedies in many of these cases, and he believed that one cause of its efficacy was that the patient was thereby prevented from lying on his back, and thus the irritation of the neck of the bladder by the accumulated urine was to some extent prevented. With regard to the mechanical treatment of enuresis by pressure on the urethra and dorsum penis, as recommended by Trousseau and other French authorities, or by the simpler and older plan of tying a tape or string tightly around the penis of a child thus affected, which he had seen adopted by some nurses in this country, he (Dr. More Madden) disapproved of it, and in cases of older children thought this practice most objectionable on obvious grounds, being not only degrading to the nurse who performed the operation of thus ligaturing the penis, but likely also to be injurious to the moral habits of the child. A plan of treatment in obstinate cases of enuresis which resisted all other remedies had been recommended in that hall some years ago by one to whom they all justly looked up with respect and esteem as *facile princeps* amongst them. He alluded to the use of collodion as suggested in these cases by Sir Dominic Corrigan, and though the value of that treatment was unquestionable in cases of incontinence of urine in very young children, and had been borne testimony to by other speakers that night, yet, for his own part, he would fear to extend even that form of mechanical treatment to those older children who were sometimes subject to this disease. The remedies which he had seen most benefit from in the cases of incontinence of urine were tonics, especially sea-bathing and iron. The tincture of perchloride of iron and belladonna in minute doses were the medicines he had most faith in. In the Children's Hospital he had treated a number of cases by means of those two remedies, and although they acted very differently they could be combined with great advantage. If they blistered the sacrum, used tincture of iron, and tincture of belladonna, stopped giving meat, and no salt in the food, they would have few incurable cases of incontinence of urine.

Dr. HENRY KENNEDY felt pleased at the discussion that his paper had caused. He did not know that he had anything to which specially to reply. So far as regarded the observations of Dr. Churchill, he (Dr. Kennedy) had never tested the urine as to its acidity. The fact of the child not being able to pass water when taken out of bed in cold weather—mentioned by Dr. Atthill—was most important.

The Society then adjourned until next session.

## GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

SESSION 1874.

THE following is the correspondence postponed from our last issue and mentioned in the Report :—

Apothecaries' Hall, July 19th, 1873.

My Lord,—The Society of Apothecaries has desired me to communicate with you on the subject of a Bill introduced by the University of London into the House of Commons for removing certain disqualifications which prevented it from uniting with any two or more bodies in a conjoint examining board under the Medical Acts.

This Bill was brought in on the 7th instant, was read a second time on the 11th, passed committee without amendment on the 15th, and was read a third time and passed on the 16th.

No doubt appears to be entertained of its being passed by the House of Lords this session.

Under these circumstances, the Society desires me respectfully to draw your lordship's attention to the correspondence which passed between the Society and the Medical Department of the Privy Council in 1872, and during the present year, and particularly to the letters addressed to the Society by the direction of your lordship on the 14th June, 1872, and the 24th March, 1873.

In deference to the suggestion contained in the letter of the 14th June, 1872, the Society did not proceed with the Bill which it was about to introduce that session.

Acting in the same spirit, the Society, as your lordship will see on referring to the correspondence of 1873, before taking any further steps itself, consulted the Government as to what its own intentions were, and received in reply the communication from the Privy Council of the 24th March, 1873. Not only did the Society attach the greatest importance to this communication (which was received at the time of the session of the General Medical Council and laid before that body), but it was regarded by the representatives of the whole medical profession as indicating the policy of the Government on the subject of medical reform.

The Society admits that this letter did not go beyond an expression of what the Government itself was prepared to do; but, undoubtedly, an inference was drawn from it that the Government would not approve any measure inconsistent with its own policy.

It would appear from the ease with which the Bill introduced by the University of London is being passed, that the inference drawn by the Society was incorrect.

I am desired under these circumstances respectfully to intimate to your lordship that the Society will introduce early next year the Bill which it had proposed to introduce last session, but which it refrained from doing in deference to your lordship's suggestion.

The Society further desires me to express the hope that in promoting this measure it will receive from the Government the same facilities as have been accorded to the University of London during the progress of their Bill.

I have the honour to be, my Lord,

Your Lordship's very obedient servant,

(Signed) JAMES RICHARD UPTON,

Clerk of the Society of Apothecaries.

The Lord President of the Privy Council.

Medical Department of the Privy Council Office,  
July 31st, 1873.

SIR,—I am directed by the Lord President to acknowledge the receipt of your letter of the 19th instant, informing his lordship that the Society of Apothecaries intends early next year to introduce the Bill which it had proposed to introduce last session, and expressing the hope that in promoting this measure the Society will receive from the Government the same facilities as have been accorded to the University of London during the passing of their Bill.

In reply, his lordship directs me to inform you that, if such a Bill were introduced by the Society next session, no general measure of medical reform being then before Parliament, the Government would take the same course with regard to it as they have taken with regard to the University of London Bill of this session.

I am, Sir, your obedient servant,

(Signed) JOHN SIMON.

The Clerk to the Society of Apothecaries.

Apothecaries' Hall, London, E.C.,  
5th June, 1874.

My dear Sir,—The Society of Apothecaries has given the fullest consideration to the views expressed on the part of the Branch Medical Council as to the Society in their present Bill, obtaining a similar power to that obtained by the University of London last year, namely, the power to make examination by the Conjoint Board an indispensable condition of being qualified to be registered as an apothecary under the Act of 1858.

I may state that the personal feelings of the members of the Society would probably be entirely in accordance with the views entertained by the Branch Medical Council on this point.

The Society as a body are, however, for the following reasons, in a position of considerable difficulty.

Before any intimation of the views of the Branch Medical Council had been made to the Society they had been obliged to deal with an amendment of a serious nature, proposed by Mr. Stansfeld, with the view of protecting the alleged rights of women; and the Society had succeeded in coming to a satisfactory arrangement with Mr. Stansfeld in reference to that amendment.

I will presently point out the difference which exists between the cases of the University of London and the Society of Apothecaries.

But I will first explain that if the Society were to attempt now to introduce a proviso in their Bill similar to that which exists in the University of London Act it would be regarded by Mr. Stansfeld as an attempt to take away with one hand what had been conceded by the other, and would be resisted accordingly.

I should add that Sir John Lubbock concurs in the opinion which I am now expressing.

The Society is, therefore, unwilling (whatever the personal feelings of the members may be) to run the risk of opposition to their Bill by an attempt to introduce a proviso, which does not appear to be an essential feature in their Bill.

The following are the distinctions which exist between the position of our Society and the University of London :—

(1.) The fact of no woman having obtained a degree or licence from that body, would have rendered it difficult for that sex to obtain a *locus standi* before Parliament, so as to insist on the preservation of rights, the existence of which could not be even alleged.

(2.) As regards the two bodies in question, a comparison of the number of persons likely to be affected on the one hand in the case of the University of London, and on the other hand, in the case of our Society, will make it clear, that what could and did pass *sub silentio* in the former instance might rouse strong opposition in the latter.

It has (I understand) been urged that the two Colleges have pledged themselves, on the completion of the Conjoint Board, to abstain from conducting separate examinations.

That pledge the Society is equally ready to give if they become part of the Conjoint Board; a pledge in fact that, having joined, they will not (except under compulsion of a *mandamus*) admit anyone to a separate examination. The two Colleges themselves have at present done nothing more.

The Society, therefore, for the reasons I have mentioned, are unwilling to imperil their Bill in order to secure what does not appear to them an essential feature of it.

I take this opportunity of laying the Bill before you in the form in which it is proposed that it should go through committee, and trust that it may appear in some respects considerably improved by the alterations which have been made, principally at the suggestion of the Branch Council.

I must, for obvious reasons, ask you to regard this letter as a private communication, and as not intended for publication.

Yours very faithfully,

(Signed) WILLIAM DICKINSON, Master.

To Dr. Paget, President of the Medical Council.

At a meeting of the Governors of St. Bartholomew's Hospital, on the 22nd inst., under the presidency of His Royal Highness the Prince of Wales, Alderman Sir Sidney Waterlow, M.P., was elected treasurer of the hospital in succession to Mr. Foster White, whose declining health has compelled him to retire from the post.

**PUBLIC HEALTH.**

---

THE Medical Officer of the Local Government Board has begun a new series of his reports, of which the first is before us. We cannot but feel satisfied at this, and we hope the trusty adviser of the Government will take care that none of this series become scarce, as some of his former reports have unfortunately not been easy to obtain.

The present report is brief, but Mr. Simon takes the opportunity of expressing his views as to the future work of his department, and it is gratifying to find that he believes the transition period incident to recent legislation is now passed, and that the work will now progress with regularity.

The country has been fortunate in having so able an administrator at the head of the Health Department during these changes, and we sincerely hope Mr. Simon may long be spared to carry on the important work in which he has so long been rendering priceless services to his country. We may return to his report on another occasion, but to-day we content ourselves with stating that the story of our escape from cholera is officially told by Mr. Simon, and demonstrates that but for the efficiency of his department we should probably have suffered a severe epidemic. This alone is sufficient to entitle the Local Government Board to credit for valuable work, and is of a kind the public may appreciate.

Our readers were informed of these circumstances at the time, so that we may as well devote the remainder of this article to the views entertained respecting the diffusion and prevention of cholera as expressed in district papers submitted to the Board by Mr. Simon, who states that both the Russian and English writers have a common basis of opinion as to cholera. They have had no occasion to touch the still disputed question of the process or processes by which cholera maintains and spreads itself in its native climate of India; on the other hand, as regards the means by which it is spread beyond those limits (ordinary and extraordinary) of its endemic prevalence, educated medical opinions vary comparatively little. No competent person pretends that the power of human intercourse to give pandemic extension to cholera is irre-

spective of most important qualifications in regard of both place and time; but that, subject to these qualifications, human intercourse is the essential agent of such extension is the conclusion which almost all modern opinions now recognise, and in which Russian and English opinion are in full accord. He proceeds to point out that the facts represent the choleraic infection as becoming for European Russia, and probably tending to become for all Europe an influence scarcely to be called alien and rare, but at least comparatively naturalised and habitual, gradually assimilating itself in this respect to the familiar European bowel-infection of typhoid fever. "And," Mr. Simon adds, "the importance of the facts in this point of view seems to me to attach to them equally, whether they be explained on one supposition of their origin or the other—whether they arise, as Mr. Radcliffe's former argument would suggest, by means of repeated introductions of new infection from without, or, as Dr. Pelikan maintains, by the long persistence in vigour of each one infection that is introduced. On either supposition we have to remember, with regard to the future, the increasing facilities for infection from India which are inseparable from the developments of traffic." The possibility of a new and most deadly contagium, tending by degrees to become current in Western Europe, can hardly be contemplated without at first a feeling of dismay. As to our defence from cholera, he points out that England has abandoned quarantine as futile, and that when cholera is current on the Continent of Europe we must accept, as practically not to be avoided, innumerable chances, which, indeed, make certainties, that the same contagium will freely enter our own country. "It is," he says, "on that basis that the true defences of England against cholera have to be planned; defences not peculiar to the coast line of England, but, in principle, equally to be aimed at in each sanitary district throughout the country; defences which (as explained in the memorandum above referred to) consist essentially in those common hygienic precautions which local sanitary authorities are responsible for providing or enforcing, and, above all, in extreme vigilance in regard of the local supplies of water and the local prevention of filth. Thus, in truth, the increasing influence of cholera on the Continent of Europe is chiefly to be regarded in this country as an additional appeal to our 1,500 local authorities to move swiftly and effectively in duties which already, on other grounds, are urgently incumbent on them." In proportion as common sanitary improvement takes from typhoid fever its present deplorable and disgraceful power of spreading among our population, in such proportion, Mr. Simon believes, will England have better security against cholera than any imaginable system of quarantine could have given her, and will be able to receive with comparative impunity whatever importations of cholera-contagium may thenceforth accrue to her from abroad.

**Notes on Current Topics.**

---

**The Navy Report.**

The Navy Report for 1872 has been issued. The total numerical force of the Navy in 1872 was 46,830. Of

these, one-half were between the ages of 15 and 25, one-third were between 25 and 35, one-eighth between 35 and 45, and rather more than 3 per cent. above 45. The average number of men sick daily was 2,134, or in the ratio of 459 per 10,000 of force, being an increase compared with the preceding year equal to one per 10,000. There were 54,697 cases of disease and injury under treatment during the year, being a decrease compared with the previous year to the extent of 40 per 1,000. The total number of days' sickness gives an average of 16·7 days to each man of the force. It is a singular proof of the regularity of natural law that this is precisely the same average as that of the previous year. The total number invalided was 1,609, being in the ratio of 343 per 10,000 of force, or an increase of 23 per 10,000 in the year. The deaths were 385, being in the ratio of 82 per 10,000—a decrease of 3 per 10,000 compared with the previous year.

Out of every 100 cases of sickness 23·58 were due to diseases of the cellular tissue and cutaneous system, 21·31 to wounds and injuries, 14·86 to diseases of the digestive system, and 10·50 to diseases of the respiratory system. Of every 100 persons invalided 15·72 were for diseases of the nervous system and organs of the special senses; 13·30 for diseases of the circulatory system; and 11·80 for diseases of the digestive system. Phthisis was the cause of invaliding in 12·36 per cent. of the total number; rheumatism, 8·57; and unclassified diseases, 6·83. Wounds and injuries only contributed 7·14 per cent. to the total invaliding, but they account for nearly one-third of the deaths. Phthisis contributed 13·76 per cent. to the total number of deaths, diseases of the circulatory and respiratory systems each nearly 10 per cent., and diseases of the digestive system 7·79 per cent. Eruptive fevers gave a percentage of 10·38 on the entire mortality.

#### New Operation for Exostosis.

WE hear that Mr. Maunder has recently practised subcutaneous surgery in the true and absolute sense of the term. A female about 15 years of age, the subject of a pedunculated exostosis attached to the lower end of the femur, was unable to use her limb by reason of this outgrowth. Mr. Maunder determined to try to fracture this subcutaneously, and having seized the tumour with a broad pair of pliers, succeeded in doing so with comparative ease. It remains to be seen what will become of this detached portion of bone.

#### Mortality and the Seasons.

IN a paper lately read at the anniversary meeting of the Scottish Meteorological Society, and summarised in *Nature*, Dr. Mitchell and Mr. A. Buchan calculated the weekly average death-rate for the past thirty years for thirty-one diseases, together with the averages of "temperature, moisture, rain," &c. The influence of the varying climates characterised as "cold," "cold and dry," "warm and dry," "warm and moist," "cold and moist"—is clearly pointed out. The weekly mortality "from all causes and at all ages" shows a large excess above the average from the middle of November to the middle of April. The minimum is reached at the end of May. Then it slowly rises, and in

the third week of July, in which we now are, it "shoots suddenly up almost to the maximum of the year, at which it remains till the second week of August," when it falls rapidly to a secondary minimum in October. The summer excess in the death-rate, abrupt in its rise and fall, is "wholly due to one section of the population, viz., infants under five years of age, none of the curves for the other ages showing an excess in the death-rate from all causes." The period of the year least marked by the occurrence of the maximum mortality from any disease is the warm dry weather from the middle of May to the end of June. The general rule is thus roughly stated:—

CHARACTER OF WEATHER.	MAXIMUM MORTALITY.
Cold.....	Bronchitis, pneumonia, asthma, &c.
Cold and dry.....	Brain disease, convulsions, whooping-cough.
Warm and dry.....	Suicides, small-pox.
Warm and moist.....	Diarrhoea, dysentery, cholera.
Cold and moist.....	Rheumatism, heart-disease, diphtheria, scarlatina, measles, croup.

Deaths from cancer and liver disease show no distinct relation to the influence of the weather.

#### Sir William Fergusson.

A REPLICA of Sir William's portrait has been presented by a deputation of the subscribers to the Royal College of Surgeons of Edinburgh. Dr. Simpson, President of the College, received the deputation. Professor Douglas MacLagan, representing the subscribers, presented the portrait, which was acknowledged by the President. It will be placed in the portrait gallery of the College.

#### Anderson's University, Glasgow.

ON July 10th a large company of Andersonian students held a dinner to celebrate the termination of the summer session with Dr. Eben. Watson in the chair, when the students of the practical physiology class, in connection with the Glasgow Royal Infirmary and Andersonian University, presented Dr. Watson with an address of thanks for the services he had rendered them as Professor of Physiology.

#### Dr. John H. Webster.

AT a Court of Governors of the Northampton General Infirmary, specially convened for the election of a Physician, it was resolved—"That this Court cannot separate without cordially recognising and gratefully acknowledging the valuable services of Dr. Webster during the nineteen years that he held the office of Physician to this Institution."

#### The Relations of Master and Servant in the Profession.

THE Master of the Rolls gave a decision last week which is of considerable importance to medical practitioners and their assistants. The bill in this case—*Gravely v. Barnard*—was filed by a surgeon, and asked for an injunction restraining the defendant, who was the paid assistant of the plaintiff, from practising as a surgeon and general practitioner within certain limits. The instrument on which the plaintiff relied was a bond into which the defendant had entered with him not to interfere with the plaintiff's practice or take away his patients. The defence was that the bond was worthless to bind the defendant, there being no valuable consideration expressed

on the face of it. The Master of the Rolls, however, held that it was not for him to decide whether the consideration was or was not sufficient, so long as there appeared to be some consideration on the face of the instrument, or so long as one might be fairly inferred from the surrounding circumstances. Here the bond recited that the plaintiff and defendant had agreed to enter into the relation of employer and assistant "for so long a time as should be agreed on between them." The meaning of that was of course that either party could terminate the connection at a moment's notice, and the plaintiff, finding that his assistant, who had hitherto been unqualified to practise, was about to pass an examination which would confer that qualification upon him, offered to continue him in his employment on the same terms as before on condition that he would bind himself not to practise within certain limits. That was a valuable consideration in the eye of the law, and if the parties thought it a sufficient one, it was not for the Court to interfere, although there really was nothing to prevent the plaintiff from discharging his assistant the minute after he had signed the bond. He (Sir G. Jessel) could not help himself, therefore, and must grant the injunction prayed for, although if he allowed his feelings to override the law, he should certainly have refused it.

### Failure of the Conjoint Scheme for England.

WE have always had our fears of a hitch, and although optimists still express confidence in the result, it appears to us that the following report of a Committee on the Bye-laws of one of the bodies is most serious. This report was presented to the Council of the Royal College of Surgeons, and adopted at the special meeting held on Friday, the 17th inst. :—

#### "Report of the Committee on the Bye-laws."

"The Committee on the Bye-laws, having in view the legal difficulties which have arisen in the carrying into effect the Conjoint Scheme for an Examining Board in England, met this day to consider the mode of overcoming these difficulties, the legal advisers of the College being in attendance at the request of the Committee, in order to facilitate their deliberations. The Committee, after long and careful consideration of the question, adopted the following recommendation as their report, to be laid before the Council at the extraordinary meeting on the 17th inst., viz. :—

"The Committee recommend to the Council that a communication be addressed to the Committee of Reference, with a request that it may be made known to the several medical authorities co-operating for a Conjoint Examination in England, that the Council of this College are advised that, under the restrictions of its charters, the College cannot legally take part in the proposed Scheme for a Conjoint Examination, unless for that examination the members of the Court of Examiners appointed by the Council of this College, or so many of them as may be required for the examination in Surgery, are *ex officio* the examiners in Surgery."

"JOHN HILTON, Chairman.

"July 14th, 1874."

### "A Pressing Subject."

IN the *Pictorial World* of Saturday last there is an admirable illustration of Sir James Paget delivering a lecture in the theatre of St. Bartholomew's Hospital on "Maladies produced by Boots and Shoes," our contemporary

not inaptly styling the picture "A Lecture on a Pressing Subject." The likeness of the eminent lecturer is excellent, and there are many faces amongst his audience we recognise without much difficulty. Sir James Paget is represented holding the cast of a foot in one hand, whilst upon the tables in front and at the side of him are casts of various malformations, with the fashionable boots which cause them. Altogether the effect is a very happy one, and our illustrated contemporary must be congratulated upon the production of a picture so full of life-like interest. The other portions of the same journal are equally excellent, and with such a formidable rival our old friends *The Illustrated London News* and *The Graphic* will do well to look after their laurels. We may add, for the information of those who desire to read the lecture "On a Pressing Subject," that it has been in course of publication during the last three numbers in our excellent contemporary *The Students' Journal*.

### The late Dr. Gray of Broadmoor Asylum.

THE force of a good example is beautifully illustrated in a passage in the Chaplain's Report, appended to the Medical Report of the Criminal Lunatic Asylum at Broadmoor. We extract the passage to which we refer :—

"Dr. Gray, the Assistant Medical Officer, having died in the asylum on the 27th February, 1873, the Office for the Burial of the Dead was said in the chapel on the day of the funeral, and the service was attended both by many officers and patients.

"I desire, Sir, to place upon record an expression of the respect which I entertained for the late Dr. Gray, and of the pain caused by his death to myself, in common with all classes of persons connected with this asylum. A gentleness of character, not without necessary firmness, had produced a strong feeling of regard for him among the whole body of the patients; and when his death was known among them, many requested to see the body. It was thought well to accede to this request; and the coffin was placed in the chapel uncovered, while all who wished to do so were permitted to pass by it in order. Some who availed themselves of the permission were among the very worst characters in this asylum; and I can recall to my recollection no incident during the whole of my long intercourse with criminals more remarkable than the sight of men indurated in crime, and with passions often ungovernable under the excitement of madness, standing to gaze in silence for the last time upon the lifeless countenance of one whom they had respected, with a sympathy which could not be concealed.

"In the discharge of my duties I have continued to receive the most cordial support from the superintendent and from the other officers of the asylum."

### The English Conjoint Examination.

THE *British Medical Journal* says: "We believe the difficulty may be considered to be satisfactorily solved. It is probable that students registered on and after the 1st of October next will receive notice that they will be required to pass under the Scheme of the Conjoint Examining Board."

THE Government of India have sanctioned a proposal for the establishment of a medical school at Rajputana, to qualify a number of young Rajputs in surgery and medicine, so as to enable them to afford medical aid to their countrymen, who are now beginning to appreciate the value and importance of European medical treatment.

### The Irish Pharmacy Question.

OUR readers are aware that the Committee of the House of Commons have closed their sittings. Their report is not yet presented, and we have, therefore, no positive information as to their recommendation. We quote, however, a statement from the London correspondence of the *Dublin Freeman's Journal*, which our readers will accept *quantum valeat*.

"Mr. Errington's Apothecaries' Licences Bill Committee have to-day decided upon their report, of which I am able to give you a *résumé*. Admitting at the outset that a Pharmaceutical Society for Ireland is much required, and that the country possesses ample material for the constitution of such a body, the Committee recommend that the Government should introduce a bill (in lieu of Mr. Errington's original bill) empowering the Lord Lieutenant in Council to appoint, in the first instance, a certain number of foundation members, who shall form the nucleus of and draw up rules as to qualifications, examinations, &c., for an Irish Pharmaceutical Society. Such society, when constituted, shall be a perfectly independent body, on a footing equal to the English society, possessing co-ordinate and reciprocal powers with the latter body—that is to say, that while itself independent, members of the English society may practise in Ireland, and members of the Irish body may practise with equal rights in England and Scotland. The new society will be formed mainly on the basis of the English body, and members of the governing council will be elected for three years. With regard to dispensing chemists, the Conservative members of the Committee carried a resolution recommending that in future licences should be required for the compounding and sale of poisons, but by the action of the Liberals a suggestion is made, by which those now compounding and dispensing poisons need not take out licences, but that this system shall apply to such chemists as may hereafter wish to dispense such articles. When the report has been presented, you will be able to publish its *ipsissima verba*, but it may be added that the bill recommended by the Committee will not be introduced until next session."

Apropos of the forthcoming report we note the following statement, made by Mr. Reuben Bolton, of Belfast, the Secretary of the Association of Licentiate Apothecaries:—

"I wish to mention that two gentlemen representing the Licentiate Apothecaries in Ireland, one from Belfast, the other from Cork, presented themselves for examination before the Committee, but were informed that their evidence was not considered necessary.

"I believe I express the feeling of those whom they represented when I characterise the refusal of their testimony as most unfair to the class whose prospects would be most materially affected by a change in the law respecting pharmacy in this country."

We gave expression a couple of weeks since to the apprehension that this most important matter would be dealt with in a flurried way, and on the authority of very insufficient evidence, and so it has turned out. The Apothecaries' Hall has had its say, the Druggists have had theirs, and the College of Physicians, through Sir Dominic Corrigan, has had its; but the practitioners in the Irish provincial towns are entirely unheard, except so far as Mr. Macnamara can be said to be entitled to express their views; and the Licentiate Apothecaries have not been allowed to open their mouths at all. Indeed, so far as we know of the evidence, the general feeling of the medical profession and the dispensers throughout Ireland is as yet unknown to the Committee. We anticipate as a possibility that the whole question may have to be reopened in the next session of Parliament when the Bill of the Committee comes to be introduced, and the battle perhaps again fought out; meanwhile, the Association of Chemists and Druggists of Ireland, after many months'

flirtation with the Apothecaries' Hall, have almost approved the following programme:—

"That this Society approves of the extension of the English Pharmacy Act to Ireland as a fair and satisfactory settlement of the pharmacy question, with these provisos:—

"1. That all at present engaged at the business, whether on their own account or not, be entitled to register themselves as chemists and druggists.

"2. That all at present engaged at the business, whether on their own account or not, be allowed to compound prescriptions and become members of the Pharmaceutical Society by passing the modified examination.

"3. That a branch of the Society be established in Dublin similar to the one in Scotland."

### The Forthcoming Meeting of the British Medical Association at Norwich.

THE arrangements for this assembly are fully announced in the last issue of the *Journal of the Association*. It will commence on the 11th of August, the President being Sir William Fergusson, and the President elect Edward Copeman, M.D., Senior Physician to the Norfolk and Norwich Hospital.

An Address in Medicine will be given by J. Russell Reynolds, M.D., F.R.S.; in Surgery, by W. Cadge, Esq., Surgeon to the Norwich Hospital; and in Obstetric Medicine, by James Matthews Duncan, M.D., F.R.S. Edin.

A *soirée* will be given in St. Andrew's Hall on Wednesday evening, August 12th, and will consist of music, scientific exhibitions, paintings of the Norfolk and Suffolk School of Artists, and refreshments.

#### EXCURSIONS.

On Friday afternoon, parties of ladies and gentlemen, accompanied by gentlemen able to give information, will be formed to visit—

1. The Cathedral (where a paper will be read), and other places of antiquarian interest near at hand.

2. The Waterworks, Filtering Beds, Reservoirs; the Sewerage Works and Farm; Bishop Hall's Palace (now the Dolphin Inn); also, on the route of this excursion, will be seen the remains of the City Walls at St. Benedict's Gates, Chapel Field, and Ber Street Gates.

3. Cossey Hall and Park.

Later on in the afternoon, J. J. Colman, Esq., M.P., kindly invites the members of the Association to a *déjeuner*.—All intending to accept Mr. Colman's invitation, whether members of the Association or ladies accompanying them, are particularly requested to notify this fact as early as possible to Mr. W. Barnsby Francis, St. Clement's, Norwich.

On Saturday there will be excursions for members of the Association and ladies—

1. To Wells, Holkham Hall and Park, the Danish Camp at Warham, Binham Priory, and Walsingham Abbey.

2. To Swaffham, Castleacre Priory, Houghton Hall, and Raynham Hall.

3. To Aylsham Church, Blickling Hall, Felbrig Park, Beeston Hills, and Cromer, returning by Gunton Park.—The Marchioness of Lothain kindly invites members who join this excursion to a luncheon at Blickling Hall.

4. To Fulton Road, joining the next party.

5. To Herringfleet and Somerleyton Hall.

As special arrangements have to be made for carriages to convey the parties joining these excursions, the numbers must be limited, and tickets cannot be issued after Wednesday, August 12th.

6. There will be also a Yacht Excursion, which will be limited to the accommodation afforded by the yachts at the disposal of the Excursion Committee.

Members wishing to join any of these excursions are desired to communicate early with the Honorary Secretary of the Excursion Committee, Mr. W. Barnsby Francis, St. Clement's, Norwich.

The following places of interest in the neighbourhood of

Norwich may be conveniently visited by members and ladies during the meeting: Yarmouth; Lowestoft; Cossey Hall; Caistor, by Norwich; Thetford; Whymondham's Geological Stations at Bramerton, Thorpe, Horstead; Botanical Stations at Horsford and St. Faith's. Hunstanton and Sandringham can also be visited from Norwich in a day.

In Norwich, amongst the objects of most interest are the Cathedral, which is open daily; forty-two churches, those most worthy of a visit being St. Peter's, Mancroft; St. Giles's St. Stephen's; St. Johns, Maddermarket; St. Gregory's; St. Michael at Plea; St. Michael at Castany; St. James's; and St. Peter-per-Mountergate; &c. Amongst the ancient buildings, are St. Andrew's Hall, the Guildhall, the Castle (now the County Gaol), St. Helen's Hospital, the old Bride-well (now a tobacco manufactory), Bishop Hall's Palace (now the Dolphin Inn); the Old Well in St. Laurence, recently restored; and the remains of the City Walls, standing in various places. Mousehold Heath is a short distance from the city.

During the meeting, the following places will be open to members of the Association on presenting their cards of membership: The Public Library; the Literary Institutions; the Free Library; the Norfolk and Norwich Hospitals; the Eye Infirmary; the Children's Infirmary; the Bethel (a charitable institution for lunatics); St. Helen's Hospital (a charitable institution for decayed tradesmen); the School for the Indigent Blind; the Norfolk and Norwich Museum; the Guildhall, with the City Plate; the Castle (now the County Gaol); the City Gaol; the County Asylum; the Waterworks; the Sewerage Works and Farm; J. J. Colman's Works; Bolingbroke's, Claburn's, and Willett's; the Yarn, Power-loom, and other factories; Barnard and Bishop's Ironworks, and many others.

A DEATH from chloroform occurred a few days since in the Leeds Infirmary. The man was under the influence of drink.

HER MAJESTY'S GOVERNMENT has decided that no further recommendations shall be made as to the appointment of analysts until the subject has been considered by Parliament.

SMALL-POX has broken out in Newmarket and district, and is rapidly increasing. The local authorities have applied to the Jockey Club for the use of the Grand Stand as an hospital.

THE Royal Naval and Marine Hospital, at Chatham, was officially inspected last week by Sir Alexander Armstrong, K.C.B., Director-General Navy Medical Department, who subsequently visited the dockyard.

AN International Pharmaceutical Congress will be opened at St. Petersburg on the 13th of next month. One of the principal questions for discussion will be the formation of an International Pharmacopoeia.

WE very much regret to observe that the begging petition put forth by Dr. Maunsell, of Dublin, for public alms for the widows of Irish Poor-law medical officers has been sent by him to her Majesty, and remitted to the Irish Government for consideration. Thus the Poor-law medical officers of Ireland—gentlemen who, we believe, respect their own position and that of their wives, and who are, at least, independent of public charity and incapable of suing for it in the whining tone of this petition—are placed openly before the public and the authorities as destitute public servants. On their behalf we earnestly repudiate and protest against their being so represented by

a few wire-pullers. The Irish Poor-law Medical Service is without doubt an ill-paid and hard-worked drudgery, and great sacrifices must be made and are daily made by its members to provide for those dependent on them; but we do not forget that they are none the less members of a gentleman's profession, and their wives usually ladies by birth and education, and we are certain that but few will be found amongst them who would accept the pittance which might be obtained by a degrading mendicancy.

In this matter at least Dr. Maunsell has entirely misunderstood the feelings of the Irish Poor-law medical officers, and has placed them in a very disreputable position by his misrepresentation of their sentiments.

WE learn by telegram that in some places in Prussian Silesia cholera is said to have broken out. The Austrian Minister of Commerce has required managers of railways communicating with Prussian Silesia to take precautionary measures. In Austria and Hungary no cholera has as yet appeared this year.

THE Infanticide Bill, which has passed the second reading of both Houses of the Legislature, enables a jury to convict a mother of causing the death of her infant under a minor clause, and of limiting the punishment from two years to ten, instead of, as now, under the capital offence of murder. To our minds this is very nearly offering a premium to child murder. The murderess is to be relieved of this dreadful sounding word and to be charged with felony.

SOME three weeks ago a mad dog made its appearance at Wigginton, near Tamworth, and bit two sheep belonging to Mr. Hodgkinson, farmer. The sheep have since been kept penned up by their owner in order to see what effect their injuries would have upon them. On Saturday week one of them showed symptoms of rabies, which gradually increased in intensity until Tuesday, when the animal's suffering became so pitiful that it was killed. No similar symptoms have as yet appeared in the other sheep.

INSPECTOR-GENERAL JOHN DAVIDSON, C.B., M.D., has been appointed Honorary Physician to Her Majesty, *vice* Sir Alexander Nisbet, deceased. Dr. Davidson is L.R.C.S. Edin. (1838), M.D. St. Andrew's (1845), and M.R.C.P. Lond. (1860). During the Russian war he was attached to the naval hospital at Therapeia, in Turkey.

Staff-Surgeon George J. Willes, M.D., from H.M.S. *Agincourt* to H.M.S. *President*, *vice* Watson (period of service expired).

Staff-Surgeon Fysher Negus, from half-pay, to H.M.S. *Agincourt*, *vice* Willes.

Surgeons George Bolster, William Inman, M.D., M. D. Hurlstone, and H. Macdonnell, to be Staff-Surgeons (second class) in H.M. Fleet.

Deputy Inspector-General William Macleod, M.D., has been re-appointed to the Royal Naval Hospital, Yarmouth.

## Literature.

### SYPHILIS OF THE NERVOUS SYSTEM. (a)

THIS is a most useful work, and another proof, if any were wanted, that there are several chapters to be added to the description of that strange disease syphilis, which has been called by some the plague of the 19th century.

Patients, says the author, frequently present themselves for advice who are suffering from some form of nervous disease dependent on syphilis, who have already received all kinds of treatment except one directed to the basis of their disorder, and who recover, or are more or less benefited when specific remedies are adopted. No doubt in some cases the amelioration is only partial; a disorganisation of nerve substance has taken place which is irreparable as far as this has gone, but further extension is prevented.

We must not expect always, says Dr. Buzzard, to find in the patient any definite sign which would necessarily prove the syphilitic nature of the malady. The peculiar grouping of the symptoms is often sufficient to point to the diagnosis. The age of the patient is of much importance in the diagnosis of syphilis. Dr. Buzzard observes that he has little hesitation in stating his conviction that, putting aside cases of injury, hemiplegia, and paraplegia occurring in a person between 20 and 45, which is not associated with albuminuria or embolism, is in nineteen cases out of twenty the result of syphilis. He has been in the habit of prescribing iodide of potassium very early in every case of palsy which did not from its symptoms offer a ready solution of the cause of the disease. Many syphilitic cases are unaffected by moderate quantities of iodide of potassium, some requiring the use of mercury.

Among cases of epileptic character he has met with there have been several in which, after bromide of potassium had failed to be of service, the iodide was successful. These were probably of syphilitic causation, as he has tried the iodide in manifestly non-syphilitic cases without good effect.

If pain in the head be associated with syphilitic attacks it generally precedes the outbreak in syphilitic convulsions, and is often localised in a spot, and has perhaps been felt for months previously. In simple epilepsy pain follows the fit, and is diffused over the forehead; in simple epilepsy the attacks most frequently commence at puberty; in the syphilitic, generally when the patient is past 20 or 25. In syphilis very often the attacks are without loss of consciousness, or the tongue may be twisted to the side and the cheek spasmodically drawn up. In syphilitic epilepsy there is frequently a rapid recurrence of seizures, with intervals of more or less considerable coma, and often loss of power in the limbs on one side following the attacks, and lasting for a short time only. Double optic neuritis, with atrophy of the optic disc, with unilateral convulsions, most frequently in the hand, imply syphilis of the brain.

In hemiplegia from syphilis the patient rarely loses consciousness; but this is not peculiar to syphilis. Gummata may exist in the brain or in the skull, vessels, or meninges. If in bone there has probably been pain felt for some time previously. When the corpora striata and optic thalami are affected the hemiplegia is most well marked; when sudden, it can hardly depend on exostosis; or when intermitting and accompanied by aphasia.

In cases of paraplegia there is not the same precision attained that has been attained in hemiplegia dependent on syphilis; still, syphilitic inflammation and gummy deposits occur in the cord. Paralysis of both upper and lower extremities may occur from cerebral meningitis or tumours in the middle line of the brain, as from a lesion within the spinal column; but generally

speaking, when in the brain such lesion generally produces mental disturbance or paralysis of some cranial nerve. The sensation of a hoop around the body points most significantly to disease of the cord. Twenty, thirty, or more years may have elapsed from the first sore ere nerve disease is set up.

Vertigo is a frequent symptom in syphilitic disease of the nervous system, and is often continual, yielding rapidly to specific remedies.

Hemiplegia with palsy of one or more cranial nerves, especially the third, fourth, fifth, or sixth; hemiplegia with paraplegia; amaurosis with convulsions, or hemiplegia or paraplegia; mental disorder with convulsions, or palsy of some nerve, or hemiplegia, or paraplegia—such are groupings that point towards syphilis.

When the lesion is syphilitic in character various parts of the patient's brain and spinal cord are from time to time affected, and the intellectual faculties become disturbed. Patients not above the middle age of life go about as chronic invalids, with one or more of their limbs paralysed, and with impaired mental powers, indolent, slovenly, and stupid. They eventually sink into dementia, or mania.

Dr. Buzzard thinks such cases have been often compounded with "general paralysis of the insane," but the latter disease has a definite course of some months up to three years, and commences with trembling of tongue and lips, and marked mental derangement. The motor disturbances are bilateral, and not so marked at first as to be paralysis. The occurrence of inflammation of the membranes covering the hemispheres, with subsequent thickening and narrowing of the vessels, occasioning softening, will cause a disorganisation capable of explaining the mental as well as the physical troubles in syphilitic dementia.

Melancholia and dementia are often syphilitic. The ophthalmoscope is most useful in cases where syphilitic nerve disease is suspected; it may indicate tumours in the cranium by the optic neuritis caused by it, and there may be disseminated choroiditis, with small white spots in the posterior segment of the eye (atrophy of the choroid). There may also be atrophy of the disc. Graefe says that 75 per cent. of the cases of disseminated choroiditis are syphilitic in their origin.

Descending optic neuritis may co-exist with pretty good vision, and may indicate the occurrence of a gummy tumour in the meninges or brain.

Paralysis of one of the muscles of the eyeball is a very sequel of syphilis, and most important in its diagnosis. Ptosis shows that there is palsy of the upper division of the third nerve, or strabismus may be caused, and diplopia.

If palsy exists in a limb with marked atrophy and complete abolition of Farado-contraction in the muscles, with exaggerated reaction to the intermitted constant current, we may safely assume that there is lesion of the nerve trunk, and not central paralysis. This is not unfrequently met with in syphilis. The same fact diagnoses the palsy from wasting paralysis.

In chapter ii. the author treats of the pathology and morbid anatomy of syphilitic nervous affections. In many cases no lesion of the skin, &c., can be seen where nervous disease exists. He does not think he has seen any instance of the more severe syphilitic nervous affections occur sooner than two years after infection. Lancereaux says that secondary affections of the nerve centres are marked by symptoms but little differing from those of sub-acute inflammation. The pia mater being similar to the iris, may be supposed to be affected sometimes with inflammation similar to that membrane.

Long after brain disturbance in the form of palsy and convulsions had been referred to syphilis it was thought that the cranial bones must first of all become affected; but there may be affections of the membranes, the vessels, or the brain. The pia mater may be affected, and adhesion of the dura mater to the surface of the brain has been considered pathognomonic of syphilis.

(a) "Clinical Aspects of Syphilitic Nervous Affections." By Thomas Buzzard, M.D. London: J. and A. Churchill. 1874.

Dry caries of the skull may be caused by inflammation of the dura mater in its external table. Obstruction of the internal carotid artery has been noticed as well as of the meningeal vessels, and thickening of the walls of the vessels has been seen.

The gummy tumour of the brain is most often found on the surface or just below it. Entire convulsions may be transformed into whitish-grey indurated tissue. The cranial nerves have been found pressed upon by yellowish-grey gelatinous transparent masses covered with an indurated envelope.

In chapter iii. the author gives some interesting cases of nerve disease which have fallen under his notice, such as those of dyspepsia, headache, epilepsy, mania, and vertigo. Epileptiform attacks in children the author suggests may be of syphilitic origin. Some of the histories are a little obscure, and doubtless would be debated were they placed before a society; but in others the case is clearly made out, and the results of specific treatment are sometimes very satisfactory indeed.

In chapter iv., which treats of prognosis and therapeutics, Dr. Buzzard states truly that the treatment of syphilitic nerve disease is sometimes most satisfactory when early in occurring. When gummata occur in the brain, &c., the prognosis is more serious.

Persons who have had secondary symptoms often escape tertiary syphilis; but there is always a possibility of these occurring: hence treatment should be resumed when any relapse occurs. If the syphilitic nature of the disease be overlooked the patient often falls into a hopeless condition. Dr. Buzzard agrees with Ricord in prescribing mercury in the primary and secondary periods of syphilis and iodide of potassium in the tertiary period. It is not so easy however to be sure when nervous disease is of the secondary and when of the tertiary period. He therefore usually commences with iodide of potassium, and gives large doses; if this fail in three or four weeks to cure, he gives mercury in the form of perchloride, or red iodide in solution of iodide of potassium. Blue pill or grey powder may occasionally be given.

Iodide of potassium may be given, sometimes 30, 40, or even 90 grains, thrice daily. Dr. Elliotson used to give 2 drachms thrice daily. The iodide may be used as freely as the bromide. Iodism in the shape of nasal catarrh does not occur more frequently after large than after small doses, and even this frequently subsides very soon. He "knows of nothing in all therapeutics more extraordinary than the rapid effects of iodide of potassium in improving the condition of these patients." We quite agree with the author in this opinion. It need only be dissolved in water. In great cachexia with lardaceous changes neither mercury nor iodine succeed.

Such is a *résumé* of this most excellent little treatise. We heartily and cordially recommend all who desire to be considered practical clinical physicians or surgeons to peruse this excellent work.

will, I assume, be conceded that this Bill, if passed into law, will assign fresh and important duties to those bodies, and will render it impossible for any of them to continue to allow the previous sanitary legislation to remain in abeyance, and it will be further conceded that these duties will be of a nature to require for their proper performance that the boards charged with them should be provided with constant and accessible medical advice and direction.

Now, Sir, I venture to state that the provision made by that clause to supply such medical advice will not merely fail to supply it, but will either cause the Act to remain a dead letter, or else introduce inextricable confusion into its working. For what else can be expected where each sanitary body will be supplied with a dozen conflicting advisers, not one of whom will be within accessible distance, and every one of whom is already provided with duties that may at any moment confine him for days together to localities twenty miles away from the board-room.

This same 10th clause entirely ignores the very existence of workhouse medical officers. These gentlemen have hitherto discharged, and will without doubt continue to discharge, the duties of officers of public health in rural unions. Thus, for instance, when an epidemic of small-pox threatened to break out in the C. Union in 1872, the board of guardians never thought for an instant of applying for advice and direction as to how the epidemic was to be met to the distant and inaccessible medical officer in whose district its first ravages made themselves felt. Instant action was requisite, immediate attendance on the hastily-summoned board indispensable, and the presence of an official whose duties might at that moment have brought him and detained him miles from the board-room was utterly impracticable. Instinctively, therefore, they turned to the medical officer placed in constant and immediate attendance on them. That which happened in the C. Union in 1872 has happened in all other rural unions under like circumstances, and will from the nature of things continue to happen. No board of guardians will in like emergency ever dream of summoning the dozen or more conflicting medical advisers which they are to be supplied with for their guidance and direction. Fancy the condition of, say, the Dublin corporation on the occasion of some threatened outbreak, with the Babel of medical advisers whom the proposed clause would substitute for the single eminent officer of health they have at present, and you have the condition that rural sanitary authorities will be placed in, with this addition, that whereas the Babel of advisers in the case of the Dublin corporation will be within an accessible distance of the board whose misfortune, or good fortune, it will be to be distracted between the attractions of so many charmers, the country Babel will be found residing at such distances as to render their united presence impracticable almost at any time, and their individual presence unattainable within reasonable limits of time. The truth is, that unity and proximity of medical advice will be found to be indispensable in the carrying out of the very large powers with which it is proposed to invest the different sanitary authorities. It is true that power is given to the Local Government Board to remedy these evils by asking the local boards to appoint a superintendent officer, or other sanitary officer; but any one at all acquainted with the spirit which pervades those boards will know that any such attempt on the part of the Local Government Board will meet with one universal chorus of opposition from every board in the kingdom, as the one main idea of all such authorities, in the present state of popular education on sanitary subjects, will be to resist all additional expense, and to work the Act or Acts with the sole regard to the minimum of expense. It is only reasonable to suppose that the Local Government Board, which felt itself obliged to give way before a partial opposition when it was a question of making a single appointment for supplying pure drugs to the Poor-law hospitals and dispensaries, will not find itself able to resist the unanimous protests of local boards against any such additional appointments referred to. The simple plan—the plan which would be found at once just and practical—would be to appoint each workhouse medical officer the officer of health for the entire union, and (with) the different dispensary officers for local officers for their respective districts. The truth is, clause 10 is the embodiment of the views of certain amateur sanitarians in Dublin who have never yet obtained the slightest familiarity with the working of any board of authority outside the limits of the city in which they reside. I may mention in conclusion that I was recently favoured with a printed communication from

## Correspondence.

### THE PUBLIC HEALTH (IRELAND) BILL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I will thank you to afford me space for some remarks on clause 10 of the Public Health Bill. I am induced to trouble you with these comments because hitherto all criticism of the Bill has been confined to metropolitan members of the profession, and because no criticism has been bestowed on the Bill by any country medical officer who, like the writer, is by the nature of his duties conversant with the local working of the former Acts and with the spirit and ideas of those rural sanitary bodies to whom the working of the present Bill, if it become law, will have to be entrusted. It

two of those gentlemen, in which they modestly assured me that they were doing all they could for us, while at the very time their small efforts were being directed to exclude us from all share, save an unrecognised and unremunerated one, in the working of the Act.

Yours, &c.,

A WORKHOUSE MEDICAL OFFICER.

### EXAMINATION REFORM IN THE IRISH COLLEGE OF SURGEONS.

THE vote of censure of the General Medical Council upon the examination of the Irish College of Surgeons has electrified the profession in Ireland, and has been received at the same time with a consciousness that it was not unmerited, and with an impression that its motive and object was not altogether without prejudice. Everyone admits, even the councillors and examiners who smart under the castigation, that there is truth and force in the reprimand of the visitors, and it is confessed that reform has been too long trifled with, and must at length be carried into effect thoroughly and literally. We learn, indeed, that the Council has already made a move in the matter. But it is also felt that the virtuous indignation of Sir William Gull was not stirred to as great an effervescence by the visitors' reports on the Scotch licensing bodies as it was by their condemnation of the Irish College. The prevailing feeling in the Irish metropolis is that the Medical Council was glad to make the most of the peccadilloes of the Irish College, but could not see the sins of other licensing bodies in the same light.

It is right also to say that the Court of Examiners of the Irish College of Surgeons are not primarily or principally responsible for the existence of the reprehended system. They might, it is true, have effected the necessary reforms if they had cared to suggest the *modus operandi* to the Council, but it was not within their jurisdiction to make any radical change, and, on the whole, they have the credit of carrying out an extremely imperfect system, with every anxiety to do their duty, and perhaps as well as such a system could be made to work.

The visitors and Sir William Gull may, however, be excused if they have permitted a little personal prejudice to tincture their proceedings in the matter. They have undoubtedly put their finger upon a real and unendurable blemish, and have done excellent service by exploding the clique in the College who have hitherto devoted themselves to the no-reform policy.

In the House of Commons on Monday, in reply to Dr. Lush, Mr. Gathorne Hardy stated that the subject of the pay and allowances of the Medical Service was under his consideration.

THE *Hospital Gazette* understands that Messrs. Golding-Bird and Jacobson have been appointed Assistant-Demonstrators, Mr. Frederick Durham, Surgical Registrar, and that Mr. Davies-Colley will take the Operative Surgery Class at Guy's Hospital.

A SOMEWHAT novel case occurred at Lennoxton, Stirling, on Thursday. A young cow had been grazing in a field in which rifle practice had been going on. As the animal died very suddenly, a post-mortem was made, which disclosed the fact that it had been feeding upon the fragments of spent bullets, the stomach being loaded with twelve pounds of lead.

## Medical News.

**Royal College of Surgeons of England.**—The following gentlemen were admitted Members of the College after examination on the 21st and 22nd inst. :—

Atkinson, Francis E., Albion Place, Leeds.  
Cobbold, Charles S. W., M.D., Portsdown Road.  
Cotton, Holland John, M.B., C.M., Edinburgh.  
Cree, William Edward, L.S.A., Upper Holloway.  
Davey, Charles James, Witham, Essex.  
Davies, Elijah Knox, Stroud.  
Davies, Francis Thomas, L.R.C.P. Ed., Pendleton.  
Erith, William E. N., Camden Road.  
Farley, John Jay, M.D., McGill Coll., Canada.  
Fothergill, John Alexander, Alfred Place, W.  
Fowler, James Kingston, Arlington Street, W.  
Frost, William Adams, Ladbroke Square, W.  
Gibbons, Robert Alex., M.B. Edin., Edinburgh.  
Gresham, Frederick C., Springfield, Lancashire.  
Gwatkin, Owen, Brighton.  
Hallam, Walter, Sheffield.  
Hardy, James Arthur, Adelaide, South Australia.  
Kirby, Samuel J. J., Stratford, Essex.  
Knox, Charles F., Trinidad.  
Lendon, Edwin Hardin, Maidstone.  
Low, Charles Arthur, Wimborne, Dorset.  
Jones, Richard Sorton, Bangor, North Wales.  
Martin, John M. H., St. Helen's, Lancashire.  
Newman, Charles, Bristol.  
Phillips, Edward J. M., Liverpool.  
Priestley, Clement Edward, L.R.C.P., St. Faith's.  
Robson, Arthur W. M., Leeds.  
Rowntree, William G., Copenhagen Street, N.W.  
Soundby, Robert, M.B. Edin., Edinburgh.  
Shuter, James, B.A., B.M., LL.B., Holloway.  
Spitta, Edmund Johnson, Clapham Common.  
Stevens, Frederick G., Kingswood, Bristol.  
Taylor, George G. S., L.K.Q.C.P.I., Springfield.  
Thomson, Peter James, Harrington Street, N.W.  
Travers, Otho Robert, Cheam, Surrey.  
Vores, William Mallam, L.S.A., Yarmouth.  
Walker, William Samuel, L.R.C.P., St. Leonard's-on-Sea.  
Webb, Charles Ford, Stockwell, Surrey.  
Whately, George F., L.S.A., Great Berkhamstead.

The following gentlemen passed on the 23rd inst. :—

Briggs, George J., Hull.  
Watts, Fred., Plymouth.  
Boese, William F. F., L.R.C.P. Lond., Plymouth.  
Bott, Henry, Bourne, Lincolnshire.  
Miller, Robert Bickersteth, Torrington Square.  
Shepherd, Francis John, M.D., McGill College, Montreal.  
Lindsay, William Vickress, L.S.A., Pimlico.  
Brown, Walter, Tetbury, Gloucestershire.  
Forty, Daniel Herbert, Shillingford, Oxon.  
Griffiths, Cecil Neil, Cheltenham.  
Job, John, Redruth, Cornwall.  
Twort, William Henry, L.S.A., Upper Canton Place.  
Carter, Albert, L.S.A., South Lambeth Road.  
Hamerton, George Albert, L.S.A., Peckham.  
Morton, Andrew Stanford, M.B. Edin., Edinburgh.  
Davison, Rashell Thomas, Tritlington, Northumberland.  
Hawken, Giles L. L., L.S.A., Camelford, Cornwall.

### NOTICES TO CORRESPONDENTS.

MR. FRANCIS VACHER, Birkenhead.—Paper "On Certain Improvements in the Hinged Short Forceps" received.

MR. LAKE.—We have seen but two numbers of the "Church Stretton Lunatic Asylum Magazine," the last about twelve months back. We believe there have been none others published, the reasons for which we must refer you to Dr. Hyalop, the Editor, Church Stretton, who may perhaps be able to induce some of his literary prodigies to write this foreing weather. We observe from a local paper they played a cricket match the other day regardless of the fact that windows are made of glass, and turned somersaults for a flower in their button-hole or a feather in their cap to the tune of a passing stream.

NEW MEDICAL JOURNALS.—Two new journals have started into existence during the past week, named respectively *The Paris Medical Record* and *Echo de la Presse Médicale*. The former is printed in Paris, and is the only medical journal in the English language published in

France; the latter is published in Paris also, but in the language of the country. The one is chiefly occupied with translations from the French journals into English; the other with translations from the English into French. Both are fortnightly, and we wish them success.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Pray pardon me for sending the enclosed correspondence.

Yours obediently,

29 Beaufort Street, Chelsea,  
July 22nd, 1874.

EDWARDS CRISP.

General Council of Medical Education and Registration,  
July 20th, 1874.

SIR,—I write to inform you that the Medical Council has been compelled to conclude its session before it could take into its consideration all the subjects referred to it.

And that, under these circumstances, the Business Committee of the Council has directed me to return to you your communication (enclosed herewith) dated the 18th inst., since it is impossible that any answer could be given to it other than that which has repeatedly been given to similar communications from you before.

I am, Sir, your obedient servant,

Edwards Crisp, Esq., M.D.

FRAS. HAWKINS, M.D.,  
Registrar.

P.S.—Your note and addendum has been placed in my hands since the foregoing letter was written; but I return herewith the addendum, which is a part and parcel only of the subjects which the Medical Council has declined to entertain.—F. H.

To the President and Council of Medical Education and Registration.

I infer from the answer I have received that the Medical Council refuses to inquire into any misdemeanour or delinquency on the part of members of their own body, or of any councillor connected with one of the corporations; but that any member amongst the unrepresented thousands may be had up before your nearly self-elected conclave and be expelled from the Register. I will, at your next meeting, endeavour to place the matter before you in a new light.

I am, Gentlemen,

Yours obediently,

29 Beaufort Street, Chelsea.  
July 22nd, 1874.

EDWARDS CRISP.

We have received from Dr. Elliot a letter which appears to have been written for the Secretary of some Life Assurance Office. Probably the letter intended for us has been inserted in the wrong envelope. As, however, we do not know which Dr. Elliot to communicate with, the right one will oblige by directing us what to do with the letter received.

QUACKERY.—A correspondent has forwarded to us a "cheap and nasty" pamphlet of the well-known London quack doctor Hamilton, which he says is being widely distributed at the West End, and ought to be exposed. We are tired of exposing Hamilton and the gang of which he is so prominent a member; the law allows him to exist in our midst, and the Government derive revenue from the distribution of his filth through the post. Perhaps our correspondent will undertake *pro bono publico* the prosecution of the individual he so much and not unnaturally objects to; we will help him by all means in our power, but he must not omit to supply us with his name and address, which he has done on the present occasion.

COMMUNICATIONS with Enclosures, &c., have been received from Dr. Burder, Bristol. Dr. Meadows, London. Dr. Orange, Broadmoor Lunatic Asylum. The Editor of *Echo de la Presse Médicale*, Paris. Dr. West, Stroud. Dr. James, Stoney Stratford. Mr. Simon, Privy Council Office. Dr. Kirby, London. Dr. Crichton Browne, Wakefield. Dr. Günther, Munich. Mr. James C. Dickinson, London. The Secretary of the Cancer Hospital. Dr. Percival, Manchester Square. Mr. Dayman, London. Dr. Campbell Black, Glasgow. Dr. Milner Fothergill, London. Mr. Baden Bengier, Manchester. Dr. Edwards Crisp, Chelsea. Mr. Sewill, London. Dr. Airdge, Newcastle. Mr. Bailey Denton. The Secretary to the Local Government Board. Mr. Cowell, Westminster Hospital. Mr. Blackett, Society for Relief of Widows of Medical Men. Dr. Henry Finch, Colchester. Mr. Vacher, Birkenhead. Mr. Aston Scotter. Mr. Haviland, Northampton. Mr. Whatford, Brighton. Dr. Morgan, Dublin. Mr. Eschwege, London. Dr. Apjohn, Dublin. Mr. Gant, London. Mr. Tyrrell, Malvern. Messrs. Upton, Johnson, and Co., London. Dr. Edmunds, London. Mr. Gaskoin, London. Mr. Blyth, Royal Free Hospital. Dr. Marsden, London. Mr. Sloane, East Grinstead. Messrs. Nichols and Leatherdale, London. Dr. Collard, Bishopwearmouth. Dr. H. V. Carter, London. Mr. W. Berry, Wigan. Mr. Lake. Dr. Elliot. Dr. Alex. G. Burness, London. Dr. Drysdale, London. Mr. G. Barracough. Dr. Henry Kennedy, Dublin. A Workhouse Medical Officer. Dr. Scott, New York, &c., &c.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED  
Searches for Summer. By C. Home Douglas. Edinburgh: Blackwood and Sons.

On the Past, Present, and Future of Therapeutics. By R. Farquharson, M.D. London: Smith, Elder, and Co.

### VACANCIES.

Royal Free Hospital, London. Junior House Surgeon. Appointment for six months. Board and residence provided. Full particulars of the Secretary. (See Advt.)  
East London Hospital for Children. Assistant Visiting Physician. Election August 4th. Particulars may be obtained of the Secretary. (See Advt.)  
Metropolitan Free Hospital. Assistant Physician, Honorary.  
Royal London Orthopaedic Hospital. Surgeon on the Staff, Honorary. Applications to the Secretary, 315 Oxford Street, W.  
Parish of Kensington. Non-Resident Dispenser for the Infirmary. Salary, £100 per annum, with dinner on the six days of attendance. Address the Clerk to the Guardians, Marlborough Road, Kensington, W.  
Ealing. Medical Officer of Health. Salary, £75 per annum, under the Health Act. Applications to the Clerk to the Board.  
Liverpool Northern Hospital. House Surgeon. Salary, £100, with board and lodging. Applicants must address the Chairman of Committee.  
Macclesfield General Infirmary. Resident Medical Officer. Salary, £120, with board. Address the Secretary at the Infirmary.  
Newport Infirmary, Monmouthshire. Resident Medical Officer. Salary, £100, with board and lodging. Application to the Secretary.

### APPOINTMENTS.

BAXTER, E. B., M.D., M.R.C.P.L., Professor of Materia Medica at King's College, London.  
BUCKELL, G., M.R.C.S.E., Medical Officer of Health for the Camelford Rural Sanitary District.  
DUFFIN, A. B., M.D., F.R.C.P.L., Physician to King's College Hospital.  
FAIRBANK, W., M.R.C.S.E., House Surgeon to the Royal Albert Infirmary and Dispensary, Wigan.  
FAIRCLOTH, J. M. C., M.D., M.R.C.P.L., a Physician to the General Infirmary, Northampton.  
GRIFFIN, G. L., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer, &c., for the Pallaskerry Dispensary District of the Rathkeale Union, co. Limerick.  
LILLY, J. H., L.R.C.P.Ed., L.F.P. & S. Glas., Medical Superintendent of the Western Infirmary, Glasgow.  
ORCHARD, T. N., M.B., C.M., Hon. Surgeon to the Panditton Ladies' Medical Society of St. Mary's Hospital, Manchester.  
PARSONS, F. J., L.R.C.P.Ed., M.R.C.S.E., Medical Officer of Health for the Portland Urban Sanitary District.  
RAWSON, W. F., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer of Health for the North Brierley Urban Sanitary District.  
RECKLESS, A., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for the North-West District of the Sheffield Union.  
RYE, A. B., F.R.C.S.E., Medical Officer to the Dolansey Hospital, Cheltenham.  
SIMPSON, B. V., L.R.C.P.Ed., Apothecary to the Gort Union Workhouse and Dispensary District of the Gort Union.  
SMITH, T. H., L.R.C.P.L., M.R.C.S.E., Medical Officer for the Alcester District and the Workhouse of the Alcester Union.  
SYMES, W. S., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer, &c., for the Maryborough Dispensary District of the Mountmellick Union, Queen's co.  
TWEEDALE, T., M.R.C.S.E., Medical Officer for the Stainland District of the Halifax Union.  
YELLOWLEES, D., M.D., L.R.C.S.Ed., Resident Physician-Superintendent of the Glasgow Royal Lunatic Asylum.

### Marriages.

GLOUTING—CLARK.—On the 25th inst., at St. Paul's, Newmarket, J. R. Clouting, M.H.C.S., of Thetford, to Grace, daughter of J. F. Clark, of Newmarket.  
PLATT—WINN.—On the 22nd inst., at St. Mary's, Kilburn, W. H. Platt, L.R.C.P., of Kilburn, to Kate Ellen, daughter of the late W. Winn, of Lincoln.  
RED—WATSON.—On the 21st inst., at Cults, Aberdeen, Alexander Reid, M.A., M.D., of Cannonbury, London, to Annie, second daughter of the late R. Watson, Builder, Aberdeen.

### Deaths.

CLARKE.—On the 17th July, at Leahy Terrace, Sandymount, Dublin, Terence Clarke, Surgeon R.N. (retired list), aged 93.  
HOLDEN.—On the 2nd July, Geo. Holden, M.D., of Lakemead, Totnes, aged 41.  
HIRSCHBERG.—On the 15th July, at Paignton, South Devonshire, H. J. Hirschberg, M.D., aged 60.  
STEELE.—On the 11th July, H. C. B. Steele, M.R.C.S.E., of Stokeferry, Norfolk, aged 64.  
TAYLOR.—On the 22nd July, at 7 Church Street, Wicklow, James R. Taylor, M.D.  
THORN.—On the 21st June, R. L. Thorn, M.R.C.S.E., of Buckingham Palace Road, Pimlico, S.W.  
WILKINSON.—On the 18th July, at Kingstown, on her 79th birthday, Harriett, widow of the late James Wilkinson, M.D., of Blackrock, co. Dublin.  
WATTS.—On the 24th July, at The Mount, Shrewsbury, John Watts, M.D. Edin., M.R.C.S., aged 54.

### LECTURES ON BRIGHT'S DISEASE,

WITH SPECIAL REFERENCE TO

PATHOLOGY AND TREATMENT,

DELIVERED AT THE ROYAL INFIRMARY OF GLASGOW,

By D. CAMPBELL BLACK, M.D.,

One of the Physicians to the Hospital.

LECTURE V.

(Continued from page 83.)

*Theory of Uræmic Poisoning.*—Until very recently the opinion was generally entertained that one of the most formidable complications and most ominous of approaching death—viz., the epileptiform convulsions and the succeeding coma, which frequently terminate the protracted illness in cases of cachectic nephritis, were due to the retention in the blood of urea; hence the terms uræmia and uræmic poisoning, terms which ought to be discarded if a nomenclature conformable to pathological conditions is desiderated. The idea, then, that the convulsions met with in chronic Bright's disease are due to urea, is one, as I shall show you, not longer tenable.

In cases of epilepsy it may be received as a universally admitted fact that the immediate cause of the convulsions is a sudden deprivation of blood from the brain or particular portions of it; and it is well known to what an extent reflex irritation operates as a factor in the production of this condition. It may therefore be said that convulsions are produced in a twofold manner, the one physical—an interruption to the current of blood, as from embolism, &c.—the other physiological, i.e., through causes operating on the nervous centres, and in turn on the minute arterioles, probably contracting them and disturbing the normal balance of the circulation. But again, poisoned blood may lead to structural changes in the brain

as elsewhere; hence the albuminuric retinitis, so-called, disease of the vessels of the brain, and the possible contingency of cerebral hæmorrhage. All this does not militate, however, against the belief that the convulsions may be due to one or other of the retained urinary products, but that this product is urea, the facts proving the contrary are so numerous and so overwhelming that the idea cannot be rationally entertained.

While it is perfectly true that there is no such thing as complete vicarious elimination, it is equally true that between the skin and the kidneys there is a functional co-ordination neither unimportant nor very limited. Hence, in cases of anuria urea is eliminated by the skin as well as doubtless by other excretory organs. Desault therefore remarks: "Il est vrai que la nature prévient quelquefois les accidents ou retarde leur naissance en se débarrassant en partie des urines, par d'autres émonctories, tel que la peau, les oreilles, les narines, la bouche, les mamelles, l'anus, &c." Dr. Johnstone (a) mentions a case of suppression in which for some days before death the skin was all over as white as if it had been powdered; this white dust on being gathered was found to have the taste of crude sal-ammoniac. This ammoniacal salt, presuming it to have been such, might have resulted from the decomposition of urea. According to Schottin, in cases of a similar nature urea is found in pus, and milk, and the sweat may contain so much of it as to form a dust on the skin. More recently, Dr. Deininger (b) published the case of a boy, æt. 5, who suffered from anurea renalis for a whole week, and on whose skin urea was discovered. Five cases of this kind have been recorded by Jürgensen and Leube, but the issue was fatal in their cases, whereas, Dr. Deininger's patient recovered. In none of these cases are we informed that there were convulsions. But not only does the skin sympathise vicariously with the kidney but there is every reason to suppose from analogy and post-mortem appearances that the diarrhoea which is so frequent and so capricious in Bright's disease—a symptom, by the way noted by writers of the greatest antiquity—

(a) London Medical Commentaries, vol. v.

(b) Deut. Arch. Clin. fur. Med.

can be regarded in no other light than that of a vicarious flux. This diarrhoea comes on suddenly, disappears suddenly, and is little under the influence of medicinal agents; it is frequently serous, and abundant, as in cholera, and weakens the patient to such an extent that he often regards it as the major ailment.

However abundant that diarrhoea may be it does not diminish the dropsey; indeed, it is not rare to find an augmentation of both conditions concomitant.

Post-mortem examination reveals the intestinal tract either healthy in appearance or discoloured; or rather offers such slight textural alterations as not to explain their derangement during life. Bright reports a case of this description, where the duodenum was found very vascular. Hodgkin has seen the ilium very much injected and of a purple colour, but without ulceration or any alteration in the intestinal follicles. Rayer has observed the small intestine affected in the same manner, either solely in that state or conjoined with other pathological changes. Christison relates a case where the mucous membrane at the termination of the ilium and the commencement of the colon was of a chocolate colour and soft. Martin-Solon has seen the mucous membrane of the last convolutions of the ileum, the end of the colon, and all the rectum, thickened, greyish, interspersed with reddish patches, small points, and vascular arborisations. In a case of Gregory's there were red patches and ecchymoses in the small intestines; in short, the appearance which the intestinal tract presents has a close analogy to the condition of the kidney, and the other organs mentioned, as being occasionally implicated in the general morbid process. That this condition represents the elimination of material incompatible with the healthy functional action of the bowels there can be no reasonable doubt.

Not only does urea from this point of view appear not to be the immediate cause of the convulsions, but direct experiments prove that its introduction into the blood is not followed by convulsions, or if symptoms of poisoning occur that there is a marked disparity between the quantity necessary to produce these phenomena and that which is found in the blood in cases of so-called uræmic poisoning. Thus, Gallois has demonstrated that in the rabbit 20 grammes of urea must be introduced into the stomach to produce toxic effects. Bright, Christison, Schottin, and others have proved in like manner that urea can exist in considerable quantity in the blood without causing death; and Parkes, Schottin, and Mossler have shown that urea may be increased in the urine even beyond its normal quantity in uræmia. Hammond, it is true, has obtained results somewhat different, and insisting that the healthy kidney permitted the elimination of the urea injected, submitted the animal to nephrotomy. But this is assuredly a serious mutilation, and which complicates the experiment to such an extent as to nullify the results; the shock of the operation alone suffices to cause death.

Bence Jones ascribed the phenomena of uræmic convulsions (and the term may be provisionally retained for convenience sake) to oxalic acid, but the presence of this acid in the blood is doubtful, and when introduced gives rise to different symptoms.

From these considerations, Frerichs, in 1851, expressed the opinion that in the presence of carbonate of ammonia in the blood was found the solution of the difficulty. According to this authority urea encounters in the blood a special ferment which converts it into carbonate of ammonia. The existence of this ferment has never been demonstrated, and the only proofs for this view, even according to Frerichs, are a violet colouration of the blood, the presence of carbonate of ammonia in the vomited matters, and the dejections. These proofs are certainly of doubtful value, and the theory at issue must be held as unproven.

In 1860 this theory was modified by Freitz and Jaksch, who maintained that the conversion of urea into carbonate of ammonia took place not in the blood, but in the intestines, and that in this form it was reabsorbed into the blood. Carbonate of ammonia has been proved to exist normally in the blood, although in very small quantity;

and Rosenstein has remarked that in cases of uræmia the quantity therein contained is not sensibly augmented.

It is true that carbonate of ammonia introduced into the blood occasions convulsions; but to produce this effect the quantity must be large; thus, Frerichs found that it was essential to the production of these phenomena to introduce into the blood of the dog no less than from one to two grammes. Injected into the frog, clonic convulsions are produced, but not the other phenomena of uræmic poisoning, especially the epileptiform convulsions and the coma; and relatively to the weight of the animals operated on Rosenstein has remarked that to produce the same consequences in man from 20 to 30 grammes of carbonate of ammonia would be requisite, a quantity which would be easily demonstrated in the blood by chemical appliances; yet the merest traces of this agent are found in the blood of persons who die from so-called uræmic poisoning.

It is worthy of further remark that Jaksch pointed out in 1860 a distinction between the symptoms which supervene on arrested secretion of urine—or *uræmia* properly so-called—and those that follow reabsorption of urine which had become ammoniacal. To the latter he applied the term *amoniemia*. In such cases it was pointed out that the breath and urine give off an ammoniacal odour, that rigors are frequent, that vomiting is invariable; while in the former case—in uræmia of Bright's disease—neither the breath nor urine exhale this odour, there are no rigors, and vomiting may be wanting. In 1868 M. See affirmed his adherence to this differentiation. Scherer, Hoppe, and Oppler, recognising the insufficiency of the foregoing views to meet the phenomena in question, have attributed the uræmic symptoms to the retention of inferior products of oxidation, such as creatin, creatinine, leucine, and such other *extractive matters*. Oppler has found these substances augmented in the fluids of the body, and even in the muscles. Chalvet recognised in the presence of these matters an indication of diminished organic combustion, a view which again accords with that which I have advanced regarding the pathology of fatty degeneration of the kidney and liver, and the production of urea in the latter organ. While it is not possible, then, in the present state of our knowledge, to condescend with certainty on the particular agent which gives rise to the nervous complication in cachectic nephritis, we seek in vain for pathological changes in the cerebro-spinal system as invariable concomitants of this condition. It is true that in certain cases sub-arachnoid serous effusion is discovered; or, in other cases, the ventricles and base of the brain are the seat of considerable effusion. Barlow, (a) by treating this fluid with nitric acid, has obtained nitrate of urea.

Sometimes, though more rarely, there exist symptoms of genuine arachnitis—the arachnoid is thickened, or opaque; but it is noteworthy that *this condition has been found in cases where, antecedent to death, the coma and convulsions were absent*. Bright, Christison, and Gregory have observed cerebro-spinal symptoms in cases in which post-mortem examination revealed an ex-sanguine, and others in which the substance of the brain was vascular or red. In 400 cases Frerichs and Rosenstein (b) found arachnitis in only nine. That the convulsions are due to inflammatory complications is therefore an hypothesis that must be rejected.

The view adopted by Traube, and the one I believe now most generally followed, is that whatever be the disturbing agent, it acts by causing an impression on the vaso-motor nerves, whereby contraction of the cerebral arterioles follows, and consequent anæmia of the brain. It must not be concealed, however, that while this view may satisfactorily

(a) Bright, "Guy's Hospital Reports," No. 11, 1836, p. 333.

(b) Quite recently (*Lyon Méd.*) Rosenstein has noticed the coincidence of albuminuria with meningitis. In nearly all the patients of this class albumen was found in the urine in the early stages of this affection. In a considerable number of them tube-casts, blood-globules, and epithelium cells were found, just as in genuine cases of Bright's disease. The lesions found after death were similar to those of cachectic nephritis. The kidney was increased in size, the hypertrophy being chiefly confined to the cortical portion; the renal tissue was injected, and the glomeruli injected with blood, with extravasation of blood into the urinary tubules.

account for the coma, it fails to do so for the convulsions and delirium.

With regard to the urinary secretion in relation to uræmic poisoning, Bright has seen the nervous complications succeed to cases of dropsy with coagulable urine, or in cases in which the urine contained albumen, but where dropsy was absent. Christison has noticed that the complications in question were not necessarily coincident with diminished secretion of urine. He has seen coma come on in a case where the patient voided thirty ounces of urine *per diem*; on the other hand, he has seen the urine reduced to a fourth of its normal quantity without the supervention of cerebral symptoms. According to Christison, the coma may occur early, or in the advanced stages of the affection in an equal degree. The early occurrence of coma is, however, more peculiar to cases of scarlatina, and I can bear my testimony to the opinion that the gravest cerebrospinal complications may be recovered from in these cases, while in cachectic nephritis they are almost necessarily fatal.

*Varieties of Nervous Complications.*—Antecedent to the occurrence of the nervous complications, however, as a rule, the quantity of urine secreted is diminished; usually it contains less urea, the quantity is reduced from 30 to 32 grammes for twenty-four hours to 20, 10, or even 7. The chlorides are diminished in the same proportion, being reduced, as in inflammatory affections, from 11 grms. to 1 or 2 grammes; the same obtains with respect to the phosphates. On the other hand, according to Schottin and Chalvet, a marked increase of extractive matters exists in the urine; and, according to Frerichs, the quantity of albumen may be estimated at from 5 to 25 grammes. Though the quantity of urine may be about normal, its density is diminished; from 1025, which may be regarded as normal, it falls to 1015 or 1008. The acid reaction of the urine is generally feeble, except at the commencement of the disease. In the acute form of the disease the complications under consideration come on suddenly, and without warning, in many cases. In others there is sharp headache, sometimes frontal, sometimes occipital. The latter has been regarded by some as the special precursor of the convulsive form of uræmia. At the same time, there is insomnia, nocturnal agitation, symptoms which contrast strongly with the usual apathetic condition of the patient; memory is impaired, bodily movements are slowly performed, and hearing is obtuse.

Sometimes the first symptom is sudden loss of sight—a symptom which must not be confounded with a parallel condition associated with albuminuric retinitis in cases of chronic Bright's disease. Not unfrequently persistent vomiting ushers in this stage of the disease—a symptom which no condition of the stomach exists to explain. At other times an habitual diarrhoea and vomiting may be suddenly arrested, when the nervous symptoms supervene so suddenly as to justify the belief in the vicariousness of the intestinal and gastric derangement.

On other occasions local convulsions alone constitute the earliest symptoms.

However the nervous symptoms may be foreshadowed, they present in their totality such marked destructive features as to justify their division into three forms—1. *The Convulsive Form*; 2. *The Comatose Form*; 3. *The Mixed Form*; and M. Fournier adds a 4th, the *Rare Form* (*formes rares*), *Convulsive Form*. This form presents the following characteristics: It is subdivisible into three varieties—the first, the *eclamptic*, is ushered in by sudden loss of consciousness, with tonic convulsions at the outset; then the clonic form, followed by somnolency, coma, and stertorous breathing—the condition resembles very much a true epileptic seizure. There exist, however, the following differences: the absence of the premonitory cry of epilepsy; and here there is frequently a pallor of countenance. Especially in this condition is there a distinctive absence of the unilateral preponderance of convulsions so characteristic of true epilepsy; again, in these cases the thumb is not contracted in powerful formation on the palm of the hand. In epilepsy, reflex sensibility of the mucous

membranes remains; in the uræmic eclampsia it is absent. Frothing at the mouth and biting of the tongue are not usually noticed in uræmic convulsions, though rarely these symptoms are noticed. Usually, the clonic convulsions are general, but sometimes *localised convulsions* do occur, so as to constitute another variety.

(To be continued.)

## MEDICAL SCIENCE AND MEDICAL TEACHING

By GEORGE BARRACLOUGH, M.A. (Cantab.), M.R.C.S.

(Continued from page 86.)

"FIXED principles," of course, are what we want, but the great question is, How are we to get them? And in reference to this the great end, Dr. Wilks gives us very little assistance. "Attain them by the ordinary scientific rules," he affirms. But the ordinary scientific rules, as deduced from the whole history of scientific thought, tell us that there can be no true law, no fixed principle discovered without the exercise of much imagination, or "fancy," as Dr. Wilks calls it, of a theoretical character, and for the most part meditated in studies. But no methods involving the exercise of such imagination or fancy can have any weight with our author, even in face of the fact that a scrutiny of the processes of thought informs us that even in geometry considerations of a theoretical and imaginative kind preceded the demonstrations, or these latter would not have been evolved. The scientific rules, then, which Dr. Wilks designates "ordinary," must be extraordinary to others, *i.e.*, there must be something profound behind his phrases which these do not adequately reveal, and this something must be Dr. Wilks's *novum organum*. Further, in speaking with so much assurance about the ordinary rules, as if there were some universal *consensus* amongst philosophers on the subject, our monitor forgets, as I have before remarked, that very grave differences exist amongst authorities as to the rules and methods to be adopted in scientific researches. But if there is one point on which authorities agree, it is that theory must always precede the evolution of fixed principles.

When Dr. Wilks remarks, "surely we should possess our knowledge first, and theorise afterwards," to what end, we inquire, is theory conceived to be a means and an instrument? That end is not knowledge or science, for we can have this, we are informed, without theory. If, in the first place, we can have the great object to be achieved by scientific research, *viz.*, knowledge, why theorise afterwards—why theorise at all, when we can obtain the thing we want without theorising. It may be objected that knowledge does not here mean anything more than acquaintance with fact. But does knowledge ever mean anything more with Dr. Wilks? Even in face of the expression "fixed principles"—for these may mean with our author only wider familiarity with fact than we now have—when we see him reject all abstract processes of thought, all preconceptions, all creative efforts of the imagination which involve theory, we cannot help the misgiving that his doctrine consists in the view of science as only acquaintance or familiarity with facts and the observation and registration of these. Besides, we are justified in presuming that anyone employing the term knowledge without any caution or qualifying expression, would, when addressing an audience more or less scientific, use it in reference to what he conceived to be the highest and most perfect information we could acquire on any subject. Of course, Dr. Wilks has a perfect right to his own use of language, and though he here departs from received usage of a term, this is a proceeding quite defensible when it implies, as it appears to do here, a departure from received doctrine. I may venture to affirm that, with the vast majority of scientific minds, not even excepting Comte, knowledge is viewed as something very different from mere familiarity with, and registration

of, fact. Nor is the term ever employed by these authorities in a lower sense without special indication that it is not restricted to this, its merely casual sense and application. I have not excluded Comte from the list, for I do not at all see how some persons, and notably Whewell, are justified in representing Comte as rejecting all theory, and as taking his stand simply on acquaintance with fact. Such assertion does not seem borne out when, in the second volume of the "Philosophie Positive," we meet with such a passage as this: "Ceux qui font consister la science dans la simple accumulation des faits observés n'ont qu'à considérer avec quelque attention l'astronomie pour sentir combien leur pensée est étroite et superficielle." But the whole paragraph is worthy of perusal, and others might be culled from the "Philosophie" in the same interest. Whether M. Comte is consistent in all this is another question, and one into which I need not enter. I mention Comte here because a positivism somewhat similar to his, and, no doubt, in part derived from it, though even worse in character, has—especially in medical circles—struck its roots deeply amongst us, and appeals only too successfully to the worst prejudices and deficiencies of the English mind. It is by virtue of that in M. Comte which appeals to the deficiencies of the English intellect—viz., his absurd negations, which have given his writings a hold in this country similar to that which was long ago achieved by the scientific works of Bacon. But with Bacon the bane and antidote go much more freely together than they ever do in the physical writings of M. Comte; for Bacon was far from being consistent in method, and what is decried in one page is often appreciated in the next. Yet, if people would pay a little more attention to M. Comte's not unwise remarks on the gradation of the sciences, and a little less to his absurd negations, useful results might follow, especially in the medical sciences.

In all knowledge which results from ascertaining the laws of objective phenomena we must (leaving out certain abstruse considerations, which I need not mention here) have previous acquaintance with elementary fact, and if anyone chooses to call this mere acquaintance "knowledge," of course, we must have this first—no one denies it. The question, in respect of fact, is not so much one of priority as of quantity, number, and simplicity. And this question of how much or how many, can only be decided by actual trial in the direction of theory serving as guide to knowledge in the higher or scientific sense of the term. When investigating any class of phenomena, so soon as we have made acquaintance with the simplest and most elementary facts, we are in a position legitimately to apply theory. If we do not do this, it is because we are either deficient in imaginative and inventive faculty, or because we are restrained by wrong notions of method. Once admitting that any observer is in the right path of research in respect to facts, it is highly presumptuous in anyone to dictate to him the time at which he may or may not theorise. How is it that comparatively few facts are sufficient for some minds to evolve law, whereas the most unlimited number are not sufficient for others? The same facts which proved so fruitful and so all-sufficient in the hands of Kepler, Harvey, and Newton were patent to the senses of their contemporaries. But why did they prove so fruitless in the hands of these latter? We can quite easily imagine his matter-of-fact contemporaries addressing Kepler in this way: "Pray, Mr. Kepler, do you not see the advisability of giving up your inveterate habit of theorising? You have already constructed nineteen false theories about the planetary orbits, and if you make nineteen hundred more you will be just as far as ever from being helped to discover the true paths of the planets; the data are not sufficient." Well, the twentieth theory did come, and with what results to science we all know.

"Knowledge first, theorise afterwards," even in the sense of fact first, and theory afterwards, is far from being true of all fact, or, indeed, of the way in which we become acquainted with most of the facts that we want. No better illustration of this, and of the function of theory generally,

could be instanced than is afforded by Dr. Wilks himself when he records his own experiences in the following extract from his address before the British Medical Association at Birmingham: "Whilst I am on this subject I must say a word in reference to another piece of pathology, on which a dissection of the dead can alone throw a light, and one which ere this (I own a personal shame) ought to have been perfected; it is akin to the matter of which we have been just now speaking. If it be true that the morbid changes be found progressing through tissues rather than particular organs, as it were by accident, it follows that these different tissues have their own special morbid changes, and none others. What we ask ourselves, therefore, is this question, What are the morbid changes to which each tissue is liable? . . . . The morbid anatomist ought long ago to have answered the question, and, I believe, *had my own attention been directed (a) to this subject earlier*, the amount of material passing under my hand would have been simply sufficient to have afforded a satisfactory solution of it. . . . Now, if what I say be true, the primary morbid changes in the lungs are strictly limited; the epithelium may produce well-formed cells, as found in pneumonia, and ill-formed ones, as met with in the chronic degenerations, *but beyond this the lung may be incapable of alteration.*" Here, the learned doctor lets us see how he has become acquainted with a certain theory, to the effect that the different tissues of the human body have their own special morbid changes, and none others. He also affirms his belief, that had he been acquainted with this theory at a more early period of his career, the material open to his observation was quite sufficient to have verified that theory. Why, then, did he not make the very important observations required? For the simple and all-sufficient reason that he was not, at that time, possessed of the theory necessary to guide him to the observation of the facts which, for want of such a theory, escaped his observation. He was not armed with that theoretical anticipation to which Bacon attached so much importance when he affirmed, after Plato, that "a searcher must have some general notion of the thing he searches after, otherwise he could never know it when he had found it; and therefore, the more comprehensive and sure our anticipation is, the more direct and short will be the investigation." In the present case the matter of fact was present to the corporeal sense, but the theoretically instructed mind was not there to recognise it, and change crude matter of fact into matter formed, i.e., into fact useful for scientific knowledge. In regard to the above theory, which in one form or other is, I presume, a very old one, I may remark, in passing, that it appears, in the hands of our author, to require a second theory to prop it up. For instance, cancer, when occurring primarily in some tissue, is regarded simply in the light of a changed mode of existence of the tissue, without any special theory being enunciated as to the manner of the change. But when cancer occurs subsequently—in the lung, say—it is designated by our author as a "deposit," i.e., something involving the theory that the changed form of an alien tissue is conveyed bodily by some vehicle, and deposited in successive layers on the tissue of the lung, after the manner of mud and stones deposited on the sea-shore by successive waves of the ocean, and thus destroying the organ merely by its presence; or, more conformably with our author's impressed views, the altered form of a certain tissue, when it comes into contact with, or is "deposited" in, the lung, suddenly develops the most wonderful powers of propagating itself afresh, by throwing out roots, it would seem, and possibly developing a sexual system, and thus destroying the lung, not by exciting any morbid change in it, but merely by appropriating its substance through the agency of organs newly acquired in some unaccountable manner. The question we ask here is, What are the preliminary facts on which this theory is founded? Or shall we not rather say that the use of that hide-ignorance term "deposit" has simply concealed an ignorance of the absence of these necessary facts. Of all

(a) The italics are mine throughout.

the misguiding words that so abound in the pathological vocabulary, that word "deposit" has the most sins to answer for. Here, as employed by an eminent physician, it seems to imply that all diseases, even constitutional or diathetic ones, are, if secondary, of a parasitic character.

From the manner in which some people talk, we can hardly help the conclusion, at which indeed Comte seems to have arrived, that they deem the observation and registration of fact the main and perhaps only business of the man of science. Against such persons it seems almost a childish task to contend that even so low down in the scale as physical science the facts are sufficiently numerous to baffle both observation and enumeration; and we have just seen that the facts of most importance are precisely those which we are least likely to observe without the aid of theory. Abstraction and generalisation must step in, and for the forming of those generalisations which tend to the evolution of law theory is indispensable; and most of all are such processes needful when we come to deal with the complicated phenomena of life. No scientific definition of disease, it is almost needless to remark, could be framed from the mere enumeration of phenomena independently of abstraction and generalisation. When the physician, for instance, in discussing such a malady as syphilis, affirms that one person exhibits a mild, another a more severe, and a third person a varied and complicated form of the disease, if he is not a nominalist his language implies that he recognises an ideal type as the thing that science has to deal with. Of course, this ideal type, in the imperfect state of our knowledge, may be only provisional in respect to the ideal which we ought to form or strive to form. Further, What, we ask, is the nature of this conception, theory, or ideality? It is not the phenomena as manifested in one or another individual, for so (though true phenomenally) we should have as many diseases as there are individuals; we should be lost in the countless host of individualities, and scientific communication would be impossible—"Smith" and "Jones" would not serve as designations of disease. Hence we see, that though we rightly speak of the ideal conception as the disease, it is not phenomenal, though based on phenomena; nor does it, in our view, represent anything transcendental and noumenal in the manner that we have seen it do in the hands of Dr. Wilks. No higher reality can be conferred on it by mis-realising it or attempting to give it an "objective" existence beyond phenomena and independent of mind. Such a proceeding is bad philosophy, and involves a kind of metaphysics which tends to bring many legitimate processes which may properly be termed metaphysical into contempt. As a simple mental creation, the ideal conception has its own proper reality, though, of course, it may be wrongly abstracted, and hastily generalised—may be bad theory, or wrong conception, and then it is unreal, because false, *i.e.*, not truly representative of fact. But if correctly idealised it may, so far as it goes, be properly regarded as the thing we have to deal with in science, and as having, for us, a higher scientific reality than phenomena, because, if correctly theorised, it comprehends not only all known, but all the possible to be known phenomena of the subject. Thus, though containing an element that is not in the phenomena, by virtue of which it serves us as we have seen the mere phenomena cannot serve us, it is nevertheless not at variance with any of these, either as actual or possible. This is how it happens that *τό νοητόν* not only does, but must take the place of *τό αἰσθητόν*, if we are to have science or knowledge. And to this effect Bacon testifies when he declares that "the true rule of a perfect inquiry is, that nothing can be found in the material globe which has not its correspondent in the crystalline globe—the understanding, or that there is nothing found in practice which has not its particular doctrine and theory."

A good illustration of empirical helplessness is afforded by the following utterance of an eminent physician, who spoke to this effect:—"Many years ago we determined to have nothing more to do with theory, and formed a society of observation. The society has ceased to exist,

but it collected a great many valuable facts, and there they are, *but I don't know what will be done with them.*" Here we have a perfect glut of facts, and then, as only result—"I don't know what will be done with them!" How forcibly this recalls the inspired lines of a living poet:—

"For I say, this is death and the sole death,  
When a man's loss comes to him from his gain,

A lamp's death when, replete with oil, it chokes;  
A stomach's when, surcharged with food, it starves."

There are persons, it would seem, who consider that facts have some inherent power by virtue of which they can spontaneously generate knowledge or science, independently of any exertion on the part of the mind. This appears to be the case with Dr. Wilks when, though he deprecates the use of the only methods by which facts can be made fruitful, he writes: "I do not wish to under-rate the researches of those who are investigating the actions of medicines, but would hail the time when these could be found to bear fruit." In the face of such depreciation of the only fruitful methods of research, we seem to be justified in considering that the similitude conveyed in the expression "found to bear fruit" is intended to be regarded as literally true, in the sense that facts, like plants being left for a season, will spontaneously generate fruit—as if, having collected many facts and placed them in our museums with a plentiful supply of spirit, we should address them thus: "Now facts, we are about to depart for a season, and when we return, mind you bear fruit and plenty of it; alcoholic spirit you shall have in abundance, but *spiritus mentis* we have none to give you, as we do not keep that article in store—it might be dangerous. Considering the variety and utter discordance of medical experiences, empiricism can claim no advantage, in point of unanimity over theory; and theory certainly has one advantage over empiricism: it does call into play some of the higher faculties of the mind. Indeed, if simple registration of fact is to be the sole occupation of medical men in their professional labours, the sooner they betake themselves to the study of subjects which call into action the ratiocinative and imaginative powers, such as mathematics, poetry, and history, the better it will be, otherwise the results may become highly untoward. Bearing in mind that the medical profession probably draws its recruits less from the outside world than any other of the liberal professions, it would be as well to scrutinise some of our empirical families with a view to ascertain whether they have not already begun to develop, or rather degenerate into, a peculiar type of organisation through the disuse of certain faculties. Really Mr. Darwin ought to be consulted on this point, it is quite serious.

Candidly, I do not think we are in a position to hope-fully apply theory to the facts of human pathology, not because the facts are insufficient, but because they are more than sufficient, in the sense, *i.e.*, of being more than a match for us. I have before dwelt on the necessity, not merely of priority, but of simplicity, of fact; in reference to theorising, of course such language is relative. In the absence of that knowledge of the subordinate laws, or generalisations of fact, which is a needful preliminary to the fruitful study of what is higher, the phenomena of human pathology which now meet our gaze lack simplicity, are too complicated for our present capabilities. But when we have the requisite preliminary knowledge of subordinate law the facts are sufficiently simple, and are suggestive of theory that we can hope to verify. Had we a better conception of the beginnings and articulations of nature, whether morbid or otherwise, should we not commence our researches at a much humbler distance from the more complicated phenomena in a series of almost incalculable immensity. In respect to the remoter stars, want of proximity is the chief obstacle to our knowledge; but in respect to a portion of organised matter, such as constitutes our own bodies, we have proximity of the closest kind, but how profoundly difficult the acquisition of knowledge about it! Physicians have hitherto found themselves unable

to meet the difficulty of calculating the tides at certain spots on the surface of the ocean, on account of the complication of the phenomena concerned. And yet the complication here is little compared with that which is presented in dealing with some considerations suggested by the structure and functions of the most lowly organised monad in existence. If we find such difficulty in discovering "law" amongst the phenomena of merely inanimate nature, and a still greater difficulty in the simplest forms of matter where the phenomena of life come into play, how can we anticipate anything but perplexity and barrenness if we commence our search after law in the highest and most complicated forms of vital existence? If our science is inadequate to grapple with disease in a grape or potato, is it surprising that disease in man should mock our therapeutics in the way it does?

(To be continued.)

## INDIAN MEDICAL NOTES—No. XXI.

(FROM OUR SPECIAL CORRESPONDENT.)

MEERUT, UPPER INDIA,  
June, 1874.

It would be a great boon if in every large station there were means of obtaining condensed information concerning medical topography, so that common sense details could at once be mastered, instead of blundering in the dark, knocking our heads, barking our shins, or tumbling into pitfalls; in fact, expensively buying experience, well known to many, yet not recorded. Formerly, newspapers, periodicals, magazines flourished at Meerut. Where are they? Lost in the mutiny, else destroyed by the ants, the rats, or the rains. Two papers cleared £5,000 a year, the leading articles written by officers, some of whom are now in high positions. Occasionally an odd volume turns up telling of sport, flirtation, drinking, gambling, duels—amusing, yet wearily monotonous. Give me facts—medical facts. In 1846 there were 10,000 troops here, about the time when the barracks at Loodianah were blown down by a dust-storm, crushing many of the gallant 50th Regiment—the heroes of Aliwal and Sobraon. Mr. Lang, alluding to the monkey-tank at Meerut, and the extraordinary periodical pilgrimages in myriads to sacred shrines so wonderfully organised by these ancestors of ours, also states that in the cemetery, besides Artillerymen, the 8th, 11th Dragoons, 16th Lancers, Buffs, and Cameronians slept, in 1856—"Their swords are rust, their souls are with the saints we trust." Mr. Lang praises mesmerism, and for some time a hospital on this system succeeded in India. We do not throw stones at mesmerism, homeopathy, or hydropathy, at Warburgh's tincture, James's powder, or Cockle's pills, at galvanic belts, or opodeldoc; but, unfortunately, these too often are the dangerous fraudulent weapons of the charlatan, and people who blamed Elliotson did not appreciate his great discoveries. Up to the time of Lord Lake and Sir Arthur Wellesley, this station being unknown to Europeans greatly did it please Bishop Heber, spending Christmas here in 1825, to confirm 300 persons, to have many communicants, and probably more than all, to hear his own composition—that pretty hymn, "Brightest and Best," sung heartily at the Church service. When the Governor-General, Lord Auckland, passed through in 1838, the female characters of "Diana Vernon," "Juliet," and "Desdemona," at the theatre were represented by strapping tall Lancers in flaxen wigs, long ringlets, but without gloves or Grecian-bend accessories. To enliven three regiments there were but two young ladies, very pretty girls, who, leaving eight others at home, came out to their sister married in the Lancers.

Dr. Russell, during the mutiny, dining once at the Artillery mess (on his road to Agra) praises up the band as conducted by one of Costa's disciples. The glory has

since departed, the plate and the pictures scattered, some at Woolwich; still, in the opinion of old stagers who have dined everywhere, the mess is now a very good one—the food, wine, silver, glass, crockery, table-linen quite up to the mark. The medical officer doing duty here what with the remains of the library of the Bengal Artillery, billiards, whist, besides out-door pursuits, need never be dull. So long as bad cases recover, the minor worries or private annoyances can be neutralised. If he wants to marry there are opportunities—very amiable, attractive girls, warranted to stand climate, whose faces are their fortunes. A bachelor's mess-bill may be about £14; house-rent, say £5; servants, including sundries, £7; the remainder including horses, buggy, clothes, uniform, tent, canteen, vary according to chances, circumstances, or the individual. You may steal a tent, or pick up bargains at auctions, and just when horses, furniture, and necessaries have been accumulated, the order to move necessitates your sale. A married officer, at the very least, ought to have £50 a month to provide the necessities of Indian life, although poor Lola Montes, of operatic, or rather ballet recollection—a lovely girl of 15—eloped from school with a junior subaltern whose annual income only amounted to £192. Returning to original text. Lieutenant Lumsden left Meerut for Calcutta in 1819, travelling first by road, then by boat down the Ganges, 1,200 miles in eight weeks, fare, £23—a crew of nine, the boat 40 feet long, often aground on sandbanks. Troops proceeding up country would be dogged at various places by natives selling cheap arrack. In some vessels on the long voyage from England, neither colchicum, grey powder, liniments, poultices, pill-boxes, gallipots, bottles, oiled silk, nor invalid cooking arrangements were available, yet the sick list would be small, the provisions including ducks, geese, salt beef, pork, and fish. In India, calomel, opium, quinine, chloroform, ipecacuanha, castor-oil, turpentine, brandy, and essence of beef will tide over many ailments. Leeches and ice are very valuable, but "far above rubies." The sanitarian's *vade mecum* is a stout dog-whip, to coax the lazy, idle, dirty cooks, sweepers, water-carriers, punkah pullers, tattie coolers, hospital servants, milkmen—in fact, natives generally who defile everything, retard progress, defy conservancy rules, and invite the wave of pestilence. When soldiers return from exciting service in the field to listless *ennui* in barracks, the desire for fruit and vegetables is but natural. The thirsty insatiable craving for spirits has from time immemorial interfered with health and discipline; many a poor fellow struggles hard against the temptation, intensified by the jeering ridicule of comrades. To relieve the parched palate coffee is seldom good; some recommend tea as delicious, cooling, and refreshing, which nobody can deny. The objections to cheap claret-cup are the chance of adulteration leading to colic and dysentery, the difficulty of weaning either English, Irish, or Scotchmen from their old loves—brandy, whisky, or rum; all drink alike, but the Scotchman has the best constitution, the hardest head, and puts more money in the bank, the very man for India. By all accounts native liquor is being supplanted to the detriment of the excise revenue by European concoctions, probably as pernicious, if not more so; therefore, we must still use moral suasion to persuade men to drink in moderation. Just as in an English village where the railway-station has at once two companions—the church and the public-house—the civilisation here progresses. A minute analysis of the Meerut water has not yet been alluded to. Unfortunately, the inability to detect the cause of any fever, the doubts thrown upon certain tests, the want of certain reagents must be pleaded just for the present, as I am unwilling to put forward an old analysis. No evidence of sewage contamination; and the greatest stress is laid on careful filtration to avoid as far as practicable the countless hidden dangers of polluted water. Dr. Alex. Smith, alluding to the failure of the germ or fungus theory, reiterates the dangers of neglected conservancy. Very possibly fire is our chief disinfectant, for the kites,

the vultures, and the adjutants who lived on excreta or on our vile bodies poisoning the soil are now decreased in numbers. Bearing in mind that the urine of 1,500 persons in one week amounts to 2,000 gallons, how are we to separate the solid from the liquid excreta, and to disinfect the former with dry earth unless each individual co-operates. The geological formation in many places should be remembered—

1. Cultivated alluvium, a sandy loam, 1 to 5 feet.
2. Kunkur, 3 inches to 3 feet, very irregular.
3. Porous sandy clay in layers, from 14 to 25 feet.
4. Fine blue pure permeable sand, 30 to 35 feet thick.

Here is the water-level.

5. Light-coloured, mysterious, impermeable clay.

Now, 1, 2, and 3 being porous, when the ground becomes polluted by human beings, animals, filth-pits, or decaying vegetation, by burial of ourselves, or hospital excreta, the combined agencies of heat and moisture brew putrescent fever. One inventor suggests a barrack made of iron, with air compartments, and fitted like a puzzle, to pull to pieces periodically for removal anywhere, and to be cooled by a steam-engine bringing air down a lofty chimney. Some writers allude to tiled floors, which, unless well-glazed, roughened, periodically rebaked, or if indifferently cemented, constitute porous sponges retaining pestilence indefinitely, the ground below remaining pure. Slate, stone, or teak would be very expensive. Double-storeyed barracks may be eight degrees hotter than others, indeed, have been 112°; yet by closing in archways with screens, and by rigid attention to cooling appliances, the temperature has been considerably reduced. Major Pengree claims for his patent refrigerator the power of reducing temperature 17 degrees. Such topics as hill-beer, sewage-farms, the prevention of slaughter of female animals, improvements in breeding, compulsory gardening by soldiers to supply vegetables, the preservation of birds, fishes, and forests, the prevention of rinderpest, the increase of mountain batteries of artillery, the encouragement of small savings of pay, the ventilation of the workshop question, the spread of education, and above all things, the attempt to control the liquor-trade in bazaars, all affect the health of the soldier. As for books or papers, however numerous, the most popular will ever be sensational novels, or the *Police Gazette*, with thrilling illustrations.

This great country has made gigantic strides since 1857; still, an immensity remains to be done, and we all have appointed tasks.

Each man's work is elastic to a certain extent, in which some succeed, some fail, others idle at the plough. If a person has health in India there are plenty of resources to keep off rust and ennui, and in the language of Shelley—

"Life, like a dome of many-coloured glass,  
Stains the white radiance of eternity."

## Hospital Reports.

### CASHEL UNION HOSPITAL.

(Under the care of DR. LAFFAN.)

I HAVE had, within a recent period, some cases of excision and amputation in my wards. Two cases of polypus presented themselves; both were of many years' standing. One occurred in a young man, æt. 25, was of the size of a small orange, and situated on the back. I removed it readily with the *écraseur*. The patient suffered little inconvenience, and was well in a few days.

The second case of polypus occurred in an elderly female. The growth was situated on the right labia, was furnished with a long pedicle, and was somewhat larger than the last. The pedicle was ligatured, and the growth removed with the knife. The patient did well.

A case of fibrous tumour somewhat larger than either of the last two, and situated in the region known to anatomists as Cloquet's snuff-box, also presented itself for operation. The patient was a middle-aged man, a painter by trade, and had laboured for years under the inconvenience and unsightliness caused by its presence. The tumour was removed by the knife. The parts soon healed. Teno-synovitis of the sheath of the extensor tendons of the thumb followed, which produced temporary stiffness of that finger. After a few weeks, however, the man regained perfect use of it, and left well.

I have also operated on two successive occasions, within an interval of a few months, on a middle-aged man, for sebaceous tumours of the scalp. Four or five were removed by the knife on each occasion; smart bleeding ensued, but was easily controlled, and the parts readily healed.

Amputation of the two inner toes of the left foot in an elderly female has had to be performed by me in consequence of a severe burn. The toes were removed without interfering with the plantar surface. The three outer toes which were only a degree less injured, furnished by their recovery another instance of the wonderful recuperative powers of these parts. The patient has now a good stump, and can walk without any lameness.

I also had recently under my care a case of caries of the metatarsal bone and proximal phalanx of the great toe of the left foot, in a scrofulous child of ten. It produced such an effect on the constitution of the child as to imperatively require excision of the parts. The bones were removed by a simple dorsal incision. The parts healed, and the patient was restored to perfect health in a short time.

There are, I suppose, few surgeons who have not met with instances of great mischief to the hand following neglected or mistreated paranechia. A poor labourer was recently admitted by me to hospital, suffering from necrosis of the second and terminal phalanx of one of the fingers, arising from this cause. The diseased parts were removed by an incision through the dorsum of the finger. The few vessels that bled were secured by my dresser, Mr. Dwyer, and the part placed by him on a straight splint. The man left with a useful finger, which was little shorter than the rest.

The grave consequences which have sometimes followed from slight contusions about the ankle-joint have often been the subject of remark. I some time since admitted a man, æt. 60, suffering from advanced disease of the tendinous structures on the front of this joint. The early history pointed to a slight contusion of the soft parts, and the disease had subsequently extended to the adjacent bones of the tarsus. Every effort was made to get the inflammation under but without success, and after much patient trial it became evident that if the patient's life were to be preserved amputation should be performed. At this stage Dr. Russell of this city, was so good as to see the case, and concurred in the propriety of removing the limb. The condition of the soft structures of the leg was unfavourable to amputation low down. The limb was accordingly removed in the upper third. Antero-posterior flaps with near skin and fascia at the extremities were made. The stump was dressed on the antiseptic method, and general supporting treatment employed. Not the slightest attempt at reaction was ever evinced, and the patient succumbed from combined exhaustion and pyæmia on the 22nd day. (a)

I have met with two other such cases. One of them was that of an old man, and was caused by a slight blow of a hammer. I saw the man in an early stage of the disease; he left me after a few days, and returned some months later, to die from its effects.

The third case happened in a young man, and was produced also by some slight cause. I saw this case early, treated it as I would a paranechia—viz., by free incisions. The patient did well.

(a) I have to express my obligations to Drs. McCarthy and Corby for the kind assistance rendered by them in the removal of this limb.

The last case I shall mention is one of internal piles. They occurred in a female beyond the middle period; they were two in number, and of the round fleshy kind. The patient requested their removal, as they caused her intolerable pain, and ordinary remedies had failed to afford her relief. On examination, the pain was found to be due to ulceration of the apices. I ligatured one, and deferred ligaturing the second for another day. The ulcerated apices were cauterised with the fuming nitric acid. The ligature came away in due time, and both piles were found to be cured. The patient's troubles were not, however, yet over, for in three weeks afterwards dropsy came on. This yielded however in a short time to appropriate treatment, and the patient was discharged well and free from all pain.

## STUDENTS' COLUMN.

### LECTURES ON HUMAN ANATOMY.

By WALTER RIVINGTON, M.S. Lond., F.R.C.S. Eng.,  
Surgeon to the London Hospital and Lecturer on Anatomy at the  
London Hospital Medical College.

#### LECTURE XI.

*Advisability of exercising the reason in studying Anatomy and of preserving an independence of thought—Articulations of the Ribs, Costal Cartilages, and Sternum—Tabular View of the Anatomy of these parts—The Thorax as a whole—Respiration—Uses of the Elasticity of the Thoracic Parietes—Alteration in Dimensions in Respiration—Different Modes of Respiration—Variations in the Thorax at different Ages and in the two Sexes—Alteration from Disease of the Lungs—Curvatures of the Spine—Mollities Ossium—Fractures of the Sternum and Ribs—Artificial Respiration.*

GENTLEMEN,—Let me urge you, when you are studying anatomy, not to be satisfied with merely loading the memory with a mass of dry facts without definite meaning to your minds, but to inquire as you proceed in your course what is the end or object of each part, and to try and solve the question, "Why is this bone, or ligament, or muscle, or whatever part it may be which you have in hand, fashioned in this particular manner?" It may be that you will not be able always to answer the question, for there are some parts of the body with whose use in the economy we are very imperfectly acquainted, but there are many parts about which there is no obscurity, and others whose office you may learn by personal observation and reflection. The knowledge which you gain and work out for yourselves is far more valuable than any other kind of acquired information, because it results from effort which disciplines the mental powers. Next I would urge you not to accept with an uninquiring acquiescence the statements which are made either in your text-books or in the theatre. It is a wise maxim which Horace has laid down, not to swear allegiance to any master. Nothing is more common than to hear a text-book quoted as if it were an infallible oracle, and as if anything not in accordance with its utterances were necessarily an error. The student should endeavour to "prove all things, and to hold fast that which is right." I make these remarks because I think that it is essential to your progress for you to preserve an independence of thought, and to exercise your reasons as well as your memories. In no other way can your anatomical studies really improve your mental powers—in no other way can you make anatomy interesting. We study the details of anatomical structure for the purpose of ascertaining their uses and functions, and we endeavour to ascertain their uses and functions in order to throw light upon their derangements and acquire the means of applying rational remedies. So far as I may be able in the time at my disposal, I shall aim at connecting anatomy with physiology on the one hand, and with surgery and medicine on the other. Design may be better than execution, but if execution fails the design will remain for some one else more worthily to execute.

In the last lecture I dwelt minutely, and no doubt a little tediously, on the points of distinction which the individual

Ribs possess, because I am persuaded that the exact movements which occur in respiration cannot be satisfactorily determined without a thorough comprehension of the effects of the variations which we notice in the disposition of their common elements. One of the prominent anatomical and physiological discussions of the present day is the action of the Intercostal Muscles, and the movements of the Thorax in the respiratory act. No one could properly understand this subject, or read with profit the writings on either side of this scientific controversy without knowing thoroughly the relative size, shape, direction, and anatomical peculiarities of each Rib, the movements of which it is capable, and the limitations which the ligaments assign to these movements. The latter subject still remains for our consideration. It will be convenient to describe the Ligaments under the following heads:—

I. The Articulations formed between the *Heads* of the Ribs and the *Bodies* of the Vertebrae. II. The articulations formed between the *Necks* and *Tubercles* of the Ribs and the *Transverse Processes* of the Vertebrae. III. The ligaments of the Sternum. IV. The Articulations of the Costal Cartilages.

I. The *Heads* of the Ribs are joined to the *Bodies* of the Vertebrae by two ligaments; (1) the *Anterior Costo-Vertebral*, or *Stellate*, and (2) the *Inter-Articular*.

(1) The *Anterior Costo-Vertebral* or *Stellate* Ligament is attached to the front of the *Heads* of the Ribs, and derives its name *Stellate* from the fact that the fibres radiate to their points of insertion into the *Bodies* of the Vertebrae and *Inter-Vertebral Disks* like the luminous rays emitted by a star. There are three sets of ligamentous rays—a *Superior*, passing obliquely upwards and inwards to the *Body* of the Vertebra above; a *Middle*, passing transversely inwards to the *Inter-Articular Fibro-Cartilage*; and an *Inferior*, passing downwards and inwards to the *Body* of the Vertebra below. On removing this ligament, the two joints between the *Heads* of the Ribs and its corresponding Vertebrae are displayed, lined by synovial membranes, and separated by the

(2) *Inter-Articular Ligament*.—This ligament is a band of fibres which runs from the ridge between the facets on the Rib and the lower part of the *Inter-Vertebral Disk*.

The foregoing descriptions will not apply to the articulation between the 1st Rib and the 1st Dorsal Vertebra, nor to those between the 10th, (a) 11th, and 12th Ribs, and the 10th, 11th, and 12th Dorsal Vertebrae. In each of these joints the *Head* of the Rib having only one facet, and articulating with only one Vertebra, the *Inter-Articular Ligament* is wanting, and the fibres of the *Stellate Ligament*, although reaching the Vertebra above, are less distinctly divided. All the joints may be regarded as *arthrodial*, or *gliding* joints.

The motions permitted between the *Heads* of the Ribs and the Vertebrae consist of slight gliding motions forwards and backwards, and upwards and downwards, and a limited amount of rotation on a transverse axis drawn through the *Inter-Articular Ligaments*.

Both the *Stellate* and *Inter-Articular Ligaments* prevent the *Heads* of the Ribs from being separated from the Vertebrae, and will act most efficiently, according to the universal law of ligaments, in counteracting force applied in the direction of their fibres. Thus, the superior rays of the *Stellate Ligament* will oppose the separation of the upper facet of the Rib downwards and outwards from the upper Vertebra, and the inferior rays will oppose the separation of the lower facet upwards and outwards from the lower Vertebra. Both the superior and inferior rays will join with the middle in opposing the separation of the *Head* directly outwards. The *Inter-Articular Ligaments* will assist the *Stellate*, and counteract the tendency of the *Head* to ascend in inspiration; being bound to the *Disk* and to the *bodies* of the Vertebrae, the *Heads* of the Ribs will influence and be influenced by their movements.

II. The *Necks* of the Ribs are attached to the *Transverse Processes* by two ligaments called the *Anterior* and *Middle Costo-Transverse Ligaments*. The *Tubercles* of the Ribs are united to the ends of the *Transverse Processes* by *Capsular Ligaments* and by the *Posterior Costo-Transverse Ligaments*.

A glance at the Skeleton will remind you that the *Transverse Processes* of most of the Dorsal Vertebrae stand obliquely outwards, backwards, and upwards from the *Arches*. The direction of the *Transverse Processes* upwards has evident reference to the convenience of meeting the Ribs in their

(a) Reference to Gray or Quain will show the omission of the 10th from this category, and yet both anatomists state, when describing the bones, that the 10th Rib has only one facet for the single facet on the 10th Dorsal Vertebra.

passage from the Bodies of the Vertebrae, and their direction backwards enables the Ribs to make a greater posterior curve, and thereby to increase the capacity of the Chest in that direction. The *Transverse Processes* bear at their extremities concave facets covered by cartilage, and looking generally upwards, outwards, and forwards, to receive the oppositely inclined facets, which are placed on the lower parts of the Necks of the Ribs. The arthrodial or gliding joints thus formed are surrounded by *Capsular Ligaments* and lined with *Synovial Membranes*. The movements permitted are rotation and gliding upwards and downwards of the Tubercles of the Ribs, and they are limited by the *Three Costo-Transverse Ligaments* which bind the Necks of the Ribs firmly to the *Transverse Processes*. The term *Costo-Transverse* is a scientific term, because it indicates the attachments of the Ligaments to the Ribs on the one hand by the prefix *Costo* (from *Costa*, a Rib), and to the *Transverse Process* on the other.

The *Anterior Costo-Transverse Ligament* passes from the upper prominent margin or crest of each Rib to the lower border of the Transverse Process of the upper of the two Vertebrae with which the Head of the Rib articulates. Its fibres run obliquely upwards and outwards from the Neck to the Transverse Process, and will evidently prevent motion of the Neck downwards and inwards. The ligament is broad and strong, and there is often a small additional and separate band on its inner side, as well as some posterior fibres having an opposite direction.

The *Middle Costo-Transverse*, or *Inter-Osseous Ligament*, passes horizontally backwards from the lower part of the Neck of the Rib to the Transverse Process. To display this ligament the Rib must either be forcibly wrenched away from the process, or a horizontal section of both must be made. It will obviously prevent separation of the two bones, and limit movements generally.

The *Posterior Costo-Transverse Ligament* runs obliquely upwards and outwards from the end of the *Transverse Process* to the Tuberosity of the Rib. It is broad and strong, and its fibres become tense when the Rib is elevated.

An examination of the *Transverse Processes* of the Dorsal Vertebrae and the adjacent parts will exhibit interesting correspondences, some of which I have not seen noticed elsewhere. More or less distinctly marked on the anterior face of the Transverse Process may be seen a ridge, which runs outwards to the facet at its extremity. Above the ridge the surface slopes upwards and backwards; below the ridge it is hollowed. The upper part is opposite to the lower half of the posterior surface of the Neck of the Rib, and its slope allows room for the Neck of the Rib in rotation backwards; the lower part is hollowed to make room for the anterior branch of the Dorsi-Spinal Nerve, which issues from the Inter-Vertebral Foramen, and passes upwards, backwards, and outwards to the lower margin of the Rib above. The ridge on the Transverse Process separating the two differently inclined surfaces attaches the Middle Costo-Transverse Ligament. Between the inner border of the Anterior Costo-Transverse Ligament and the Vertebra is an aperture which gives passage to the posterior branch of the Spinal Nerve issuing from the Inter-Vertebral Foramen, and to the posterior branch of the Intercostal Artery. At the root of the *Transverse Process*, and between it and the Inferior Articular Process, is a Notch, or hollow, which allows room for the posterior branches of the Nerve and Artery in their journey to the back. This Notch is well seen on a posterior view of the vertebral column.

III. The *First and Second Pieces of the Sternum*, the Manubrium and the Gladiolus, are united in one of two ways. The joint formed between them is either *Amphiarthrodial* or *Diarthrodial*. In the *Amphiarthrodial* form of joint there is a single piece of Fibro-Cartilage uniting the ends of the bones, and connected by fibrous tissue with the Cartilages of the 2nd pair of ribs. In the *Diarthrodial* form of joint there are two distinct layers of Cartilage, one covering the end of the Manubrium, and the other the end of the Gladiolus. The cavity of the joint communicates on each side with the articulation formed between the lower facet on the Cartilage of the 2nd Rib and the facet on the upper angle of the Gladiolus, a common synovial membrane lining the united cavities of the three joints. The joints formed between the upper facet on the 2nd Costal Cartilage and the Manubrium is shut off from the common cavity below by the fibrous tissue which unites the salient angle of the Cartilage of the Rib with the layer of Cartilage covering the end of the Manubrium. Whichever form of joint exists, the ligaments are the same in kind and disposition; anteriorly and posteriorly there are some short ligamentous fibres connecting the ends of the

Manubrium and the Gladiolus. The posterior set of fibres are often thick, filling up a rather wide interval, which exists posteriorly between the 1st and 2nd pieces of the Sternum. Both anteriorly and posteriorly the two segments of the Sternum are joined by a thick Periosteum, which passes over the joint and conceals from view the short ligaments just described. The amount of motion permitted at the joint varies greatly, and seems to be altogether dependent rather on age than on the nature of the joint existing in any particular specimen. Sometimes it is an obscure to and fro movement, obtainable only on strong pressure, at other times there is appreciable gliding, coupled with some amount of rotation. (a)

IV. The *Cartilage of the 1st Rib* is implanted in the large depression at the upper end of the lateral aspect of the Manubrium, and its tissue is often directly continuous with the Sternum. The *Cartilages of the other True Ribs* generally form arthrodial or gliding joints with the depressions on the Sternum. In the articulations between the 2nd and 3rd Costal Cartilages and the Sternum there are, or ought to be, *two joints* lined with distinct synovial membranes, and separated by an *Inter-Articular Ligament*. In the case of the 2nd Rib this ligament passes from the Costal Cartilage either to a symphyseal fibro-cartilage between the Manubrium and the Gladiolus, or to a distinct layer of cartilage covering the Manubrium. The *fourth, fifth, sixth, and seventh* Costal Cartilages play in *single* synovial cavities. All the joints are protected by radiating *Anterior and Posterior Costo-Sternal Ligaments*, and the movements permitted are slight gliding movements of the ends of the Cartilages upwards and downwards and forwards and backwards. The analogy which has already been pointed out between the sternal and vertebral joints of the Ribs is increased by the presence of radiating or *stellate* ligaments covering the front of both. Some transverse fibres passing from the anterior aspect of the 7th Costal Cartilage to the Ensiform Cartilage are called the *Costo-Xiphoid Ligament*. All the ligamentous fibres on the Sternum are more or less blended with each other with the periosteum and with the tendinous attachments of the muscles.

Articulations lined with synovial membrane and surrounded with capsular fibres are occasionally found between the contiguous margins of some two or more of the Costal Cartilages beginning at the 6th and ending at the 10th.

The costal ends of the Cartilages are implanted in the pits at the ends of the Ribs, and the Periosteum of the Ribs is continuous with the Perichondrium of the Cartilages. The chief points already dwelt on may be exhibited in a

#### TABULAR VIEW OF THE RIBS, COSTAL CARTILAGES, AND STERNUM, AND THEIR LIGAMENTS.

##### I. Ribs.

Parts of Rib.		Corresponding Parts.	Mode of union, &c.
Head presents	1. A small facet above, covered by cartilage	Facet on upper Vertebra	Synovial gliding joint
	2. A ridge opposite and attached to	Disk	Interarticular Ligament
	3. A larger facet below covered by cartilage	Facet on lower Vertebra	Synovial gliding joint
	4. Anterior surface attached to	Two Vertebrae and Disk	Anterior Costo-vertebral or Stellate Ligament, which has 3 fasciculi

(a) The existence in many Sterna of a diarthrodial joint between the Manubrium and the Gladiolus was pointed out by M. Maisonneuve, and his observations are contained in a paper entitled "Recherches sur la Luxation des Deux Premières Pièces du Sternum," contained in the *Archives Générales de Médecine*, iii. serie, tome xix. M. Maisonneuve found the diarthrodial joint in two out of five specimens; but he does not state how many specimens he examined. He observed it more frequently in the female than in the male, and with greater frequency in the adult and aged persons than among the young. According to him, the Ensiform Cartilage remains separate from the Gladiolus up to 50 years of age, and the Manubrium up to an age still more advanced; and he believes bony union of the Manubrium and Gladiolus to be an anomaly, as he had only seen two or three examples of it. My own observations differ in some respects from those of M. Maisonneuve. The rarity of the diarthrodial joint in the young I can fully confirm, but I found it of less frequent occurrence in the female, and not so common as the amphiarthrodial form. I believe that the diarthrodial joint is formed generally by absorption after the age of puberty. Ossification of the Cartilages uniting the segments of the Sternum I have seen more frequently than M. Maisonneuve, and at an earlier age. The following are the results of examination of 100 fresh Sterna: 51 exhibited the amphiarthrodial joint and 32 the diarthrodial joint, 11 were of a mixed nature, the separation between the two segments being incomplete, and 6 had undergone ossification. For further detail reference may be made to a paper by the author, read at the Medico-Chirurgical Society in January last, and in course of publication in the Society's "Transactions."

Neck presents	1. Upper Border elevated into a Crest and joined to	Lower Border of Transverse Process above	Anterior Costo-Transverse Ligament
	2. Anterior surface, smooth, covered by	Pleura and Posterior Border of the Lung	
	3. Posterior Surface, rough, foraminiferous, joined to	Transverse Process of Vertebra below	Middle Costo-Transverse or Inter-osseous Ligament
	4. Inferior Border continuous with the ridge on the Shaft		
Tuberosity	Articular smooth facet internally and inferiorly	Facet on the Transverse Process	Capular Ligament and Synovial Membrane, gliding joint
	Rough elevation externally and superiorly	Tip of Transverse Process	Posterior Costo-Transverse Ligament
Angle (Posterior)	Point of junction of segments of 2 circles, of which the anterior is the larger. Direction of rib altered at this point. Rib strengthened at a weak point		
Body or Shaft	1. External Surface convex, marked by	Posterior Angle	Attaches Tendons of Erector Muscles of back
		Anterior Angle	Attaches muscles
	2. Internal Surface	Ridge	Attaches internal intercostal muscle
		Groove	Lodges intercostal vessels and nerves
		Foraminiferous	Attaches intercostal muscles, internal and external
	3. Superior Border, thick		Attaches external intercostal muscle
	4. Inferior Border, thin		Receives outer end of Costal Cartilage
	5. Anterior End, cup-shaped		

**Differential Characters of the Ribs.**—First 7, Vertebro-Sternal, or True Ribs; 8th, 9th, 10th, Vertebro-Costal; 11th, 12th, Vertebro-Costal, or Floating Ribs.

**Length**—Increases from 1st to 8th or 7th; Decreases from 7th to 12th. 1st and 12th nearly equal.

**Breadth**—1st widest, rest diminish gradually.

**Curve**—Diminishes from 1st to last.

**Peculiar Ribs**—1st, 10th, 11th, and 12th. Each of these has one facet only on the Head. Interarticular Ligament absent.

**1st Rib**—Surfaces—Superior and inferior Borders—Internal and external Tubercle and Angle correspond. Neck flattened from above downwards.

**Markings on the Upper Surface**

1. Groove for Subclavian Vein
2. Tubercle and Ridge for Anterior Scalene Muscle
3. Groove for Subclavian Artery
4. Impression for Middle Scalene Muscle

11th and 12th Neck, Tubercle, Angle, Ridge, and Groove, either indistinct or wanting altogether.

### II. Costal Cartilages.

2 Surfaces	Outer	Convex	
	Inner	Concave	
2 Borders	Superior	Concave	A distinct bend occurs a little after the commencement of the Cartilage
	Inferior	Convex	Implanted in cup at anterior end of Rib
Ends	Outer		Joined to Rib by Periosteum
	Inner	Narrower than outer end	Ends of first 7 joined to Sternum Ends of next 3, to each other Ends of last 3, free

Increase in length from the 1st to the 7th.  
Decrease " " " 7th to the 12th.  
Diminution in breadth from 1st to last.

### III. Sternum, developed in 6 Bony Segments.

3 Pieces after middle life	1. Manubrium = 1 Segment. 2. Gladiolus = 4 Segments. 3. Ensiform Cartilage = 1 Segment.
Entire Bone has 2 Surfaces	Anterior.—Convex, more or less arched, marked by indications of junction of segments Posterior.—Concave, marked less distinctly
2 Borders, right and left	7 Cups or Notches for Cartilages of first 7 ribs, each cup after the first, and excepting the 6th, being formed by 2 segments
2 Extremities, Superior	Episternal Notch, flanked by facets for Clavicles
Inferior	Of various shapes, being the end of the Ensiform Cartilage

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 5, 1874.

### EXAMINATIONS AT THE COLLEGE OF SURGEONS.

THE examinations at Lincoln's Inn have lately been the subject of comment in our pages, as well as in those of our contemporaries. Considering how often mishaps have befallen candidates, it is not surprising to find that at most of the schools of medicine the more zealous teachers are discussing the best methods of preventing future rejections.

The discussion has at times taken a decidedly personal turn, and at the late election to the Council we are aware that the voting was influenced by rumours as to this or that person being unduly harsh in the capacity of examiner.

Examiners of this kind are seldom altogether reliable, and we should regret any ground being given for their continual propagation; but, of course, it is impossible to prevent conclusions being drawn when unusual events occur in a certain definite direction.

Some of our anatomical teachers are known to have worked with more zeal than ever, and it is not unlikely that nearly all have done so. They have taken great pains, by examinations beforehand, to see that pupils did not go up until they were well prepared; and yet they do not seem to have been as correct in their predictions as might have been anticipated, and consequently they begin to believe in either unfairness or chance.

It has happened within our own knowledge for the best men of a batch to be plucked while the shaky ones got through, though at the same time we are free to confess that we have more frequently observed the industrious reap the reward of their work, and the idler sent back to his studies. Still, the mere fact that there is this appearance of chance in the matter shows that there are considerable imperfections in the method of testing a candidate's knowledge, and unquestionably the fact deserves the serious attention of the examining board.

In addition to the points to which we have previously drawn attention, we have good reason to believe that some good men have been rejected at Lincoln's Inn—and elsewhere too—through being ignorant of the mode adopted by the board. It is clear that method has much to do with the apparent readiness of a candidate's reply. If he had been led to believe that questions will take a certain form, and demand one kind of answer, it is obvious he may

be "taken aback" by abrupt interrogatories of another kind. For instance, a man who supposes full descriptions of parts to be expected, though full of knowledge, may not respond to the query "what's this?" by simply naming the organ shown, because he is arranging in his mind the order in which he will give a full description of it. We know one instance of this kind in which the examiner at once concluded that a candidate did not know the duodenum when he saw it, the candidate all the while thinking the examiner wanted far more than the simple name of the part when he inquired what it was. For this reason we have always advised students to bear in mind the nature of the examinations at the several boards, and we have always held that such knowledge is essential to success unless to the most brilliant men. It is for this reason that the Universities publish full instructions in their calendars, together with the questions set from year to year. No such guides, however, are published by the Colleges. For this reason we have advised students to read the chapter on the subject which forms the appendix to Gant's "Science and Practice of Surgery," and which we know to have been useful to many. Considering this, and the use of University calendars, we are glad to find that Mr. Gant has issued his remarks in a separate form, and very much extended them. The new book will be found a useful one to candidates, for the questions of the last five years are included in it, as well as a brief description of the specimens, preparations, and instruments used, and the arrangement of the examination-room. Nothing can be more reassuring to a nervous man than the power of anticipation of the kind of test to which he has to be subjected, and Mr. Gant's new "Guide to the Examinations at the Royal College of Surgeons of England" seems to us a most legitimate means of preparation. Of course, like other aids, it may be used to "cram" for the occasion by idle men, but they would find it of little value for their purpose; while diligent students will find it of real use, as it will enable them to test themselves, and they may easily extend their examination of specimens and instruments beyond the lists contained in the Guide.

## Notes on Current Topics.

### The Vice of Drunkenness.

THE state of Dublin just now, as to the habits of the lower orders, has been the subject of considerable comment in the daily papers during the past week, indeed, the tragic occurrences which have excited them could not fail to have had their effects. We find a fine girl in the prime of life dying at Mercer's Hospital from the results of a wound inflicted by her own father, so severe in its nature that it would appear from the report of the surgeon's evidence it was "a hopeless case from the beginning," and such was the loss of blood that the girl is stated to have died of "want of supply of blood to the brain" even at the end of seven days after the injury, by which it appears the common carotid artery and jugular vein were severed. Again, we find at the same hospital a case of a woman burned to death whose husband exhibited such unusual signs of barbarity and hard-heartedness that the coroner was moved to

notice it specially, and it would appear from the evidence that it was possible, if not probable, he put her out of the room in her burning clothes, and took no further trouble. Lamentable and chronic drunkenness seems to reign supreme amongst the lower orders, cleanliness is wholly unknown, rags and squalor are so habitual that they do not excite even shame: the Monday police reports testify but too largely to these debasing facts; it is not uncommon, we believe, to trace the sufferers from pewter-pot, and other engines of carouse assaults, to our accident hospitals by the blood that flowed from their wounds. The magistrates are commencing a more stringent course of punishment, and are enforcing the extra correction which the law allows to habitual drunkards. Last week the establishment of Temperance Hall, or Public House, was inaugurated; but this is, we believe, but mere surface work: the facilities for obtaining liquor by the lower orders are altogether too frequent. The large number of spirit-grocers who are allowed in addition to the regular public-houses is altogether out of ratio to the population; we are satisfied that the former are the more injurious and deadly to the people, as under the appearance of an ordinary business premise tippling, as it is styled by our police reports, is encouraged, add young men and women who might hesitate at entering the regular "public" and tap, are insidiously led on into habits of dissipation. From all we hear, we cannot but believe that there is ample room for the excise and police to exercise increased supervision in this respect, and come down sharply on such offenders as are pretty well suspected, if not actually known.

### The Working Man's Dwelling.

MR. SECRETARY CROSS fulfilled a promise made to the House early in the session when Mr. Kay-Shuttleworth moved a resolution with regard to the great necessity of improving the dwellings of the labouring classes in this vast city. The right hon. gentleman then declared that "no question out of the whole range of those which were likely to come before the House was nearer and dearer to his heart," and that he was anxious to introduce a measure with the view of securing to the working classes of the metropolis dwellings equal to those in other parts of the country.

A recent attempt of the Midland Railway to disturb the dead as well as the living, and thereby acquire the burial ground of St. Pancras, has been a means of indirectly contributing to the adoption of a new set of standing orders, which will be the means of compelling every committee of the House to see that when labouring people are about to be displaced new dwellings are provided, or at all events, that the remedy for the evils mentioned shall be at the discretion of the House.

The following resolutions to the effect were moved by Mr. Cross, and adopted by the House, on Thursday last:

1. In the case of any Bill for making any work, for the construction of which power is sought to take in any city, town, or parish, fifteen houses or more occupied either wholly or partially as tenants or lodgers by persons belonging to the labouring classes, the promoters be required to deposit in the Private Bill Office on or before the 31st day of December, a statement of the number, description,

and situation of the said houses, the number (so far as they can be ascertained) of persons to be displaced, and whether any and what provision is made in the Bill for remedying the inconvenience likely to arise from such displacement, and that such statement be referred to the committee on the Bill.

2. In every such Bill a clause be inserted to enact that the company shall, not less than eight weeks before taking any such houses, make known their intention to take the same by placards, handbills, or other general notice placed in public view upon or within a reasonable distance from such houses, and that the company shall not take any such houses until they have obtained the certificate of a justice in England and Ireland, and of the sheriff in Scotland, that it has been proved to his satisfaction that the company have made known their intention to take the same in manner required by this provision.

3. In every such Bill a clause shall be inserted, if applicable, requiring the promoters to provide, within the time limited for the completion of the work, sufficient accommodation for the persons belonging to the labouring classes who will be displaced by improvements authorised by the Bill.

4. The committee upon every such Bill shall report specially to the House—1. Whether such Clauses have been inserted in the Bill; and, if not, the grounds upon which the committee have decided them to be inapplicable. 2. The several circumstances affecting the displacement of houses by the operation of the Bill, and the means by which other accommodation is to be provided for the persons to be removed.

### Flogging Schoolmasters.

WE have unfortunately had occasion far too frequently to notice a tendency in the modern Squeers to an excessively cruel use of the rod. Whether this in any way arises from the high temperature and a consequent overheated state of the atmosphere in which schoolmasters live and move and have their being, we are quite unable to say; we, however, can scarcely conceive it possible for a properly-balanced mind, or an highly-educated man, and after due time for reflection, standing over a boy and administering 88 strokes on the bare back—such a flagellation, in fact, that ten days afterwards a surgeon “found evident marks of the severe infliction.” The head-master of Shrewsbury School is a lucky man to meet with judges who find him “*not guilty, but advise him not to do it again*”; and recommend that for the future punishments should be more in accordance with public schools.”

If a severe and uncalled-for flogging, meriting a proper rebuke from the governing body, was not inflicted upon Jeffery Loxdale, we should be glad to be informed what, in their opinion, is a severe flogging? and, as our contemporary the *Echo* observes: “Considering that young Loxdale’s offence was neither cruelty, nor theft, nor falsehood, nor any other heinous or disgraceful moral offence for which severe expiation might be deemed befitting, but only the breach of school discipline involved in having ate and porter conveyed to his study (we are not even told that he drank too much of either), and considering further that his father had brought him to make full apology to Mr. Moss, and had left him under the impression that his fault was condoned, we are somewhat at a loss to guess what amount of knouting Mr. Moss would inflict as retribution for a real sin.”

### Hospital Sunday in America.

THE Hospital Sunday movement appears to have taken a firm hold of the American mind; and we read in the *Boston Medical Journal* that the distribution of the Hospital Sunday Fund by the committee appointed was as follows:—

Massachusetts General Hospital	...	...	\$4,531.74
Carney Hospital	...	...	862.84
Massachusetts Homoeopathic Hospital	...	...	571.02
Channing Home	...	...	574.16
House of the Good Samaritan	...	...	971.42
St. Elizabeth’s Hospital	...	...	555.72
The Children’s Hospital	...	...	1,147.27
St. Luke’s Home for Convalescents	...	...	641.45
New England Hospital for Women and Children	...	...	1,146.79
Massachusetts Charitable Eye and Ear Infirmary	...	...	916.79
Boston Dispensary	...	...	829.92
Charlestown Dispensary	...	...	265.00
Dr. Cullis, Consumptive’s Home	...	...	90.00
Dr. Cullis, Cancer Hospital	...	...	200.00
Boston Lying-in Hospital	...	...	5.00
Children’s Mission	...	...	.60

Total ... .. \$13,309.96

The above distribution of the general fund is based on the number of weeks of board and treatment given gratuitously by the hospitals during their last financial year. The last four-named institutions on the list were the recipients of special contributions alone.

We learn that the amount of the London collection exceeds £29,000.

### A New Mode of Lighting Railway Carriages.

OUR contemporary the *Engineer* furnishes particulars of a new invention whereby railway carriages may be effectively lighted with gas on the longest journey. The chief difficulty hitherto has been that of storage, and even where, as on the Metropolitan Railway, the journeys are short, the impossibility of guaranteeing the gas against mixture with air, which seriously impairs its lighting power, considerably diminishes its superiority over other agents. For long journeys, the ordinary gas reservoir would be too cumbrous, and if this defect is met by the device of pumping the gas into strong retorts under pressure, so as to carry it in a smaller space, coal gas deposits carbon, loses nearly all its lighting powers, and has a way of escaping through what are called air-tight vessels. To Pintsch, of Berlin, belongs the honour of having overcome these difficulties. He abandons coal gas altogether, and makes his gas from oil. He packs it in iron retorts at a pressure of 90lb. to the square inch, and supplies it to the lamps through a very ingenious regulator. Some Continental railways have already adopted this system of lighting. In England an experimental carriage has been fitted with it on the London and North-Western Railway, and has been running some weeks. The carriage carries gas enough in a receiver, made of wrought iron  $\frac{3}{4}$ in. thick, 5ft. 10in. long, and 1ft. 4 $\frac{1}{2}$ in. diameter, at five atmospheres pressure, to run twice to Holyhead and back, sufficient gas being left for a further run to Chester, if necessary. In other words, the

carriage carries gas for over 1,000 miles. It may be imagined that the gas would waste away, or lose its illuminating power during so long a run, but this is not the case. The oil gas used is of nearly forty candle-power, and the light given in the carriage is nearly double that given by an oil lamp, while, as regards cost, this is about 70 per cent. cheaper than oil.

### A New Method for the Enumeration of Red and White Blood-Corpuscles.

M. L. MALASSEZ lately described in the *Archives de Physiologie* a method of counting blood-globules by means of certain apparatus devised by himself.

For the purpose of examination the blood is diluted with an artificial serum, composed of one vol. of a solution of gum arabic of specific gravity 1020, and three vols. of a solution of equal parts of sulphate and chloride of sodium, also of specific gravity 1020. The pipette, of a peculiar construction, called the "mixer," in which the blood and artificial serum may be mingled in any desired proportion with great accuracy, is figured and described at length by M. Malassez. For examination under the microscope a capillary tube of known volume is soldered to a glass slide, and by the aid of an eye-piece micrometer of peculiar construction, also devised by M. Malassez, and described by him in the same number of the *Archives*, the number of globules to a given volume of blood is rapidly and accurately estimated. In ascertaining the proportion of red globules the blood is mixed with artificial serum in the ratio of 1 to 100 or to 200, but in the case of the white globules the ratio of blood to serum is as 1 to 50. It is in estimating the latter that M. M.'s method is more accurate than others.

### Hinged Short Forceps.

MR. FRANCIS VACHER, in a paper descriptive of, and remarking upon, a new form of midwifery forceps, stated in last year's vol. of the *Liverpool and Manchester Medical and Surgical Reporter*, that, though convinced the principle on which his own instrument was constructed was sound, he could not pronounce it perfect. In a note communicated to the new vol. of the same series he tells us that in the course of the first delivery it accomplished, one defect, viz., the position of the button commanding the steel snap, became apparent, and since then two other flaws in the original design have discovered themselves, one, the instrument's extreme shortness, and the other, its want of some modification which would enable the operator to unlock and withdraw the blades without previously returning them into the hollow of the sacrum. These three imperfections have, with the kind assistance of Messrs. Weiss and Sons, whom he personally consulted on the subject, been corrected. The catch which locks the blades when *in situ* is now controlled from the end of the half of the handle attached to the upper or outer blade instead of from the front of the half the handle belonging to the lower blade, so that with the new instrument there is no possibility of the operator involuntarily unlocking it by the pressure of the palm of his hand during traction.

Secondly, inasmuch as this forceps is intended for effecting delivery of the head when in the pelvic cavity, no less

than when it has in great part passed through the outlet, it has been found necessary to increase its length by removing the clams a little further from the handle by the introduction of strong shanks an inch and a quarter in length.

Thirdly, it having been pointed out that, should delivery prove impracticable after traction had been sufficiently long tried, it would be an advantage to be able to separate the blades, and remove them right and left in the ordinary way, the hinge rivet has been fitted with a head to allow of its being readily drawn.

The inventor believes that the new pattern is the smallest, lightest, and most portable short forceps devised.

### Irish Pauperism.

It appears from the Annual Report of the Irish Local Government Board that the increase of nearly 3,000 persons in the pauperism of Ireland (as represented by the admissions to workhouses), in the year 1873 has disappeared since this time last year, and the country has returned nearly to its previous condition. The number of workhouse inmates on a selected day in 1873 was 54,125; in 1874 it was 51,161.

The Board attributes this fluctuation wholly to the wetness of the season 1872-73, and the injury done thereby to the potato and turf harvests.

### Deaths in Irish Workhouses.

THE total number of deaths in the workhouses in the last year has been 11,801. The total number of deaths for 1872-73 was 11,672, which, compared with the present numbers, shows an increase of 129 of deaths, and an increase of 1,218 compared with the number in 1871-2.

The number of deaths by fever is 663 in comparison with 655 in the previous year, and with 678 in the year preceding.

It will be seen that 110 deaths from small-pox have taken place in the workhouse hospitals of Ireland in the course of the year 1873-74 in comparison with only one single case recorded for the year 1869-70, and with only 13 in the year 1870-71. In the following year, 1871-72, the number was 462, and in 1872-73 it was 677, the epidemic having prevailed during a portion of each of these years.

### New Use for Nitrate of Amyl.

THE *New York Medical Journal* contains an important case in which this drug was tried on a patient who seemed dying. We extract the particulars:—

I. H., aged thirty-two years, labourer, entered the service of Dr. E. G. Janeway, at Bellevue Hospital, on May 27th, 1874. The history obtained was to the effect that, during the summer of 1872, he first noticed his eyelids to be puffy, and his feet swollen. He continued to work, however, until five months before admission, when increasing debility, complicated with dyspnoea, palpitation, and loss of appetite developed. When admitted, the patient was anæmic, very pale, and stated that his urine had been suppressed for forty-eight hours. His feet and legs were very œdematous, and the rest of his body to a slighter extent. There was increased area of cardiac dullness, with a double murmur over heart anteriorly and posteriorly, with the qualities of a friction-sound of cardiac rhythm. There were also evidences of slight œdema of the

lungs. The catheter removed only a few drops of urine from the bladder. Dry cups were applied over the lungs and kidneys, and half an ounce of infusion of digitalis, with half a drachm of acetate of potassa, given every four hours. The next morning the dyspnoea was improved, and about four ounces of highly-albuminous urine passed. About noon Dr. Janeway saw the patient for the first time. He was then unconscious. Pupils dilated. No response on touching the conjunctiva. Complete loss of pulse at the wrist, and breathing of a spasmodic character, such as occurs a few minutes before death. Some nitrite of amyl was obtained, and inhalations of five drops, cautiously increased to twenty-five drops, commenced. After the use of twenty drops, the pupils began to contract, and winking resulted from touching the conjunctiva. The pulse now began to be felt at the wrist. With the use of the last five drops he returned to consciousness, and the pulse at the wrist became full. He was now able to speak, and asked how long he had been faint, and whether or not he would pull through. The inhalations were now suspended, and half an ounce of brandy administered. A man was stationed at the bedside to notify the house-physician of the least approach of dangerous symptoms. In about fifteen minutes another attack occurred, and by the time the physician approached him he was dead.

There can be no doubt that in this case the amyl produced the temporary restoration from all but death, and the subsequent death in so short a time showed the gravity of the case.

This temporary restoration might be at times of great value, and, in a case where the lesions were not so serious, might be prolonged into cure and permanent recovery.

Dr. Janeway has not read of any case in which such a near approach of death was warded off, and is of the opinion that, as a rule, it would not be judicious to give such large doses; but, from the fact that a certain amount remained on the towel, it is difficult to say how much in reality the patient inhaled. He does not believe that the nitrite would prove equally serviceable in cerebral hyperæmia producing unconsciousness, the case under observation being one of cerebral anæmia, with failure of the heart's action from pericarditis.

*Autopsy.*—Lungs cedematous, with slight hydrothorax. Heart normal in size. Pericardium coated with fibrinous exudation of considerable amount. The sac contained a small quantity of serum. A microscopical examination of the tissue of the heart showed evidences of fatty degeneration in the portions beneath the pericardium. Liver, fatty. Kidneys, of the large, white variety. Evidences of fatty degeneration, with increase of connective tissue. Cortical part of the kidneys anæmic. On one side there was a hydrocele.

### The Adulteration of Beer.

DR. SEDEJACK gives the following in the *Journal of Medicine*, Brussels:—

According as beer consumption increases, so does its adulteration; this has hitherto been done in secret, but now no difficulty is made, for a *fabricant* of the adulterations now publicly announces himself. M. Rosendorf has recently sent round a circular to the brewers, both native and foreign, to whom he recommends his “*bier succédané*,” or his *bier surrogats*. He particularly recommends his grape-sugars as being economical of the malt, glycerine to correct tartness, and concentrated bisulphite of lime to prevent secondary fermentation and acidification, as well as to render beer, when turned sour, equal to its original condition; to clarify the beer he offers an assortment of tanning substances, and also to give it a concentrated tinge.

To give Bavarian beer the peculiar “bouquets” of various manufactures, he recommends tartaric acid, syrup of beet root, &c., and to crown the work he offers to

communicate to his correspondents (under guarantee of secrecy) how practically to elude extra duty.

At Munich the use of hops is getting less from day to day, and these adulterations seem to exercise a most deleterious influence on the health of the population, for it is observed, since the invasion of cholera, that on every evening on which most beer is consumed there is a direct increase in the extent of the disease—thus, on Sundays and Mondays a regular increase is found to occur, with a corresponding rise in the death-rate.”

### Modified Syphilis.

SURGEON-MAJOR PORTER, the Assistant Professor of Military Surgery at Netley, has contributed a valuable note in this week's *Medical Journal* on the subject which was originally started by Mr. Morgan, of Dublin. In the pages of this journal, the remarks made and the testings given in detail by Mr. Morgan went to prove that a modified form of sore could be produced from females not at the time at all suffering from either a primary or a secondary ulcer, that this sore assumed on syphilitic subjects always the character of the soft type, which has been by some confidently asserted to be innocuous to the system. The dualists have had their day, and still contend for a straight-laced duality; Mr. Morgan contended this point, and argued that soft sores were frequently followed by constitutional signs; that they were the result of accidental inoculation from the discharges of constitutionally-tainted females, and that the symptoms which followed were usually of a milder type than those resulting from the true chancre, and were not associated with the remarkable and intense cachexia so often seen, and what is most important to note, required a modified form of treatment. In confirmation of these views Mr. Porter now gives the following *résumé* of his experience:—

“For many years after joining the profession, I was led away by the belief that there were two forms of primary venereal sores, “*infecting*” and “*non-infecting*”; the former followed by secondaries, the latter not so. After some experience in the army, at home and abroad, I found I was frequently disappointed in my prognosis; that some of the most simple sores, or excoriations, which healed in a few days with the application of cold water, were followed in due time by secondary symptoms of mild form, such as two or three coppery patches on the face and trunk, a sore throat, or cracking of the palms of the hands. Such cases completely upset my mind as to the doctrine of duality, and I came to the conclusion that, though I might almost to a certainty point out a sore which would be followed by secondary symptoms, yet I was unable to point to any simple venereal sore and say, this will not be followed by secondaries of some character.

“With regard to Mr. Morgan's theory, ‘that the vast majority of primary sores are not derived from sores, but from the inoculated discharges of constitutionally-infected women,’ I may state that when serving in Saugor, Central India, in 1865, the admissions into hospital in my regiment from venereal sores were numerous, and caused me much anxiety. At my suggestion, I was permitted to take into custody, for medical observation, the prostitutes (natives of the lowest type) frequenting the neighbourhood of the barracks and cantonments; I carefully examined them with a speculum, and sent those diseased to the civil hospital for treatment. These unfortunate women, it was well known, were the source of the disease among the troops; but I was surprised to find that nearly all suffered from a purulent vaginal discharge, and not from true syphilis, a sore being but seldom met with.

As a practical illustration of compulsory inspection he adds the following remarkable evidence:—

"The result of my endeavour to check the disease was satisfactory, as may be seen by the following figures: *Admissions*—January, 1865, 18; February, 19; March, 25; April, 22; May, 19; June, 4; July, 1. In the month of August the regiment left the cantonment in consequence of cholera. The system of supervision of the prostitutes was commenced on the 17th of May, and 15 of the 19 admissions during the month were prior to this date, 4 only having been admitted during the latter fourteen days. These figures, which I recorded at the time, and have now before me, may be found of some interest.

#### Popliteal Aneurism cured by Ligature, followed by the Reappearance of the Tumour. Cure by Injection.

M. CAUBY relates a case of aneurism the size of the fist, occurring in the popliteal space. He in vain tried cure by pressure and flexion. The patient, however, who was very intolerant of treatment, preferred ligature of the artery, which was performed at Scarpa's triangle. In a month the cure was complete, and he resumed work as an agricultural labourer. The swelling, however, reappeared in the ham, with a sense of fluctuation which was very distinct. Compression had no effect; so Mr. Cauby injected the perchloride of iron into the tumour; smart inflammation followed, and an incision was finally made into the tumour, which was found full of clots. There was no subsequent hæmorrhage, and the patient made a rapid cure.

#### The Pharmaceutical Conference.

THE programme of the Annual Conference, which commences next week, is as follows: The business and pleasure work of the meeting will extend over four days, commencing on the 5th and ending on the 8th of August. During the first three days there will be an exhibition of objects relating to pharmacy, in the rooms of the Pharmaceutical Society's house at Bloomsbury Square. This exhibition will be open on those days from ten in the morning until six in the evening.

On the evening of Wednesday next there will be a *conversazione* given by the Pharmaceutical Society, to which all members of the Conference are invited.

On Thursday the special business of the Conference will commence, as usual, at ten o'clock, with the election of new members, the reading of the report of the executive committee, and the reception of delegates. Then will follow the address of the President-Elect, Mr. T. B. Groves, and after that the reading and discussion of papers will be proceeded with.

In the evening of Thursday, the annual dinner of the members of the Conference and their friends will be held either at the Inns of Court Hotel or elsewhere, as may be found desirable.

On Friday, the reading and discussion of papers will be continued, and the election of officers will terminate the general business of the meeting.

On both these days luncheon will be provided in the upper rooms of the Society's house, between 12.30 and 2 o'clock, the local committee inviting all who attend the meetings to partake of it. In this way loss of time and trouble will be avoided.

On Saturday there will be an excursion from London to

Cliefden Wood and Maidenhead, to which provincial members of the Conference and foreign delegates are invited by the London members of the trade. A special train will convey the party by the Great Western Railway from Paddington to Great Marlow, where boats will be in readiness for continuing the journey by river through one of the most picturesque parts of the Thames valley, past Cookham Dean and Cookham to Cliefden, where, by the kind permission of the Duke of Westminster, the party can land, to ramble through the woods for a while, until it is time to return to the boats and proceed to Maidenhead Bridge, at which place luncheon will be provided.

#### JOTTINGS FROM JOURNALS.

Dz. HENRY MACCORMAC communicates to our monthly contemporary, the *Doctor*, a series of practical notes collated from various periodicals, and which he calls "Jottings from Journals." We take a few opinions from the last number:—

**CURE FOR CORNS.**—Wear sandals, or, like the Irish girls, go barefoot. The *Pacific Medical*, however, commends paring, and inunction with castor-oil. Avoid pressure, and no undue thickening of the epidermis can possibly ensue.

**BURN MIXTURE.**—Dr. Buck, of the Bellevue Hospital, dissolves 2 oz. gum tragacanth and 4 oz. of gum arabic in a quart of water; add a pint of molasses, and apply with a brush.—*New York Med. Record*.

**ARSENIC IN INTERMITTENT FEVER.**—M. Sistach, in a summary, states that he has treated by means of arsenic (*acide arsénieux*) in a very dilute form, as administered by the mouth and rectum, 229 cases—that is to say, 137 cases of quotidian fever, 73 tertian, 11 of quartan, 5 of irregular fever, and 3 of masked, and that all did well. The cases occurred at Bona, in Africa, and were reported upon by MM. Moutard, Martin, Bouillaud, and Chauffard on the part of the Académie de Médecine. In pernicious intermittent fever the treatment, as might be expected, was less successful.

**MARTIAL LEMONADE.**—Citrate of iron in plates, 1 gramme; syrup, 100 grammes; artificial seltzer water, 900 grammes.—*Le Mouvement Médical*.

**KAKKE KAKKE.**—A malady thus named, Dr. Hoffmann states in the *Japan Mail*, is endemic in Japan. It is sometimes attended with insensibility and paralysis, but more commonly trembling and debility. It disappears in winter, and is highly similar to Indian beri-beri.

**PILLS FOR CONSTIPATION.**—Take podophyllin 0.03 gr., honey 9—one dose.

**PERITONEAL ABSCESS.**—A remarkable case is recorded in *Le Progrès Médical* by M. Pasturaud, hospital intern. It was that of a peritoneal abscess between the liver and diaphragm. The contents penetrated into the right lung, and were evacuated through the bronchial tubes. The patient died. A post-mortem demonstrated the exact nature of the case.

**CORYZA.**—Dr. Prout, *New York Medical Record*, speaks in warm terms of the efficacy of 20 or 30 minims of the tincture of the perchloride of iron. His formula is—tincture, glycerine, of each up to 8 grammes, or say 2 drachms; a teaspoonful every two or three hours in a little water three or four times. He has obtained almost

immediate relief in his own case and the cases of his patients. He leaves off as soon as tokens of amendment ensue, and begins treatment as soon as possible after the onset of the coryza.

**PERSISTENT VISION.**—A curious case is related in a recent Italian medical journal. The circumstance was that of a medical man who, in the act of reading an article which greatly interested him, fell fast asleep. After slumbering for some time he awakened right up, and much to his surprise the article which he had been reading, the portion which had interested him, was impressed letter for letter, word for word, and line for line on the opposite wall. Similar occurrences have been witnessed from time to time, but rarely to so striking a degree as in the instance here adverted to.

**PERNICIOUS INTERMITTENT.**—In these countries we are happily almost exempt from intermittent fever, both simple and pernicious; but in certain so esteemed health-resorts both these forms of periodic malarious disease subsist, as many and many an Englishman and Englishwoman has experienced to their cost. There are attacks of pernicious intermittent well known both in Algiers and in Italy, in which the affected persons sink down as if stricken with apoplexy. The importance of a correct diagnosis must be obvious. In the *Giornale Veneto* Dr. Namias has described a case of this *febbre perniciosa apopletica*. The patient was plunged in complete coma, the limbs were motionless, and the left side quite cold. Leeches (*mignatte*) were applied to the mastoid apophysis, followed, as soon as the patient could swallow, with large doses, two in all, of the bisulphate of quinine. The subject left the hospital perfectly cured, a result which, unfortunately, is far from constant.

**TREATMENT OF GONORRHEA.**—There are practical remarks in the *France Médicale*, by Dr. Ferran, which are deserving of much attention. After some general observations on the treatment of this troublesome affection by means of what he terms substitutive irritation, he goes on to say that in order to obtain the most satisfactory results he employs cubebs and the balsams, not two or three times, but ten or twelve times daily. In this way there is commonly a steady amelioration of the symptoms, and in most cases a recovery in from twenty-two to twenty-six days. Dr. Ferran lays no claim to have discovered this treatment, which he has otherwise employed for a matter of ten years.

## A SECOND NOTE ON WINE.

In according to wine a certain share of our attention we follow not so much the course as the torrent of ideas; in this we yield to compulsion only, no way ambitious to display our taste or to spread the contagion of a fancy. The amount of space devoted to the subject by one of the ablest of our contemporaries might be thought to cover the whole field, and yet so evidently but a share of it; and who shall exhibit the remainder? The inspiration is evident enough. To lift us out of the old groove a powerful wrench has been contemplated, the force of rhetoric has not been spared any more than its *finesse*; a good deal besides is left unsaid, to be furnished by the intelligence of the reader. This is so apparent throughout as scarcely need be hinted at. A new commercial phase is entered on. New things require their interpreters, and ancient habitudes must stand on one side for passing fashions; to help the weak, to wage war upon the strong, the original starting point and a generous thought in the main have a little too much possessed our contemporary, impairing the criterion of his palate. On the part of the public the response is tardily given. Our wine merchant's list shows still a conservative bias; he is evidently no convert to the wine *versus* alcohol doctrine, but leans upon the old ideas,

and price serves still as a pretty fair index to quality. The gentle housewife still demands her sherry regardless of its calcareous ingredient. The pernicious fluid holds its own remarkably well, in no danger of being ousted by any article. For our hospitals and public services we observe the wine in request continues to be port and sherry, with no kind of fear, it is said, of their being supplanted by novelties or seriously injured by competition. These institutions are not precisely the best field in which to adventure an experiment or to exercise a more than fit economy. We remember some forty years since, in the days of high Customs duty, what excellent quality of wine used to be served in the hospital of our studentship, furnished by a first-class house, an excellent port—scarce any better have we tasted since, and none substantially better—the white wine perhaps in quality not so choice, but still very sound and good. Every way our hospitals then were on a more limited scale, since which time they have had extensive accretions in the way of wealth truly wonderful; but by the fatality that is peculiar to these institutions, the more they gather the more they are out at elbows, and always crying poor.

Certain it is that at the present time the wine furnished to our public services is of better class and quality and also of higher price than what finds its way into our hospitals; and some of these even condescend to Taragona or Catalan port, a wine which has this merit at least, that it gives a better profit to the vendor and leaves no shadow of obligation on the part of the institution. As to the British merchant of old type, one cannot speak too much in praise of the very liberal terms in which our hospitals have all along been dealt with. The error we have stigmatised above springs from the impenetrability of *paterfamilias*, who thinks it is impossible that a wholesome wine, genuine port, can be had at an equally moderate price with other wine of modern introduction. Accustomed himself to drink port at £60 a pipe in bond, from eight to eleven shillings a gallon, for such is the superior article to which the British householder is accustomed, he does not conceive that Oporto wine can be had at just half that price which answers all the purposes of health and convalescence—now, even so low as £25 per pipe—such port wine may be acquired and purchased at Oporto for £23—say four-and-sixpence a gallon, seven shillings with the duty paid, very little more than a shilling a bottle. But as to this half-crown duty, its removal is only a question of time; equalisation of duty is imminent, demanded by policy, national and commercial, as well as by common sense; we shall then look to enjoy to a fuller extent the benefit which has already accrued to public health in the increased consumption of wine. But the prices such as have been named above are the terms on which it will be furnished by the Douro trade. When enterprise has further opened main channels of commerce in Portugal agreeably to data furnished in our issue of June 3rd, we shall have a competition from that country of wines both red and white, which will be perfectly on a level with public taste and find a great future before them. Among the wines as yet introduced in the recent epoch of lower alcoholic strength under favour of the one shilling duty, some we have tasted are very excellent and enjoyable, but for the most part, by some fatality on inquiry, they have been rather dear, and in spite of the relief in duty the wines of a higher class we have found not cheaper or better than those of the olden time. This is our every-day experience. It is also possible to accustom oneself to the bad until the palate no longer endures or acknowledges what is good; in short, the hour seems not yet to have arrived in England when we may find wine choice and cheap. But under the change we are contemplating, that of the abandonment of an oppressive duty, that is to say, the emancipation of partial restrictions, if we may judge of the future by the past, no sudden convulsion need be feared. Those in possession will long enjoy the advantage of the ground they have acquired, for neither are our social tastes so pliable, nor is commerce so adventurous and bold as assertion might lead us to believe.

## Correspondence.

### ON THE THEORY OF COUNTER-IRRITATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In an otherwise excellent paper on this subject in the *Practitioner* for March, 1874, Dr. James Ross advances the theory that counter-irritants act beneficially, not by drawing away any diseased influences from the affected part, nor as antiphlogistics, in the ordinary sense of the word, but always by conveying a stimulus to the diseased part, either by sympathy or contiguity. As the only surviving editor of Dr. Fletcher's works, will you allow me to call attention to the fact that this is substantially the same rationale of the action of these agents as was always taught by Dr. Fletcher in his class, and is given in his "Elements of Pathology, 1842," as the following extracts will show:—

"It is absurd, then, to continue to talk of counter-irritation in the sense, at least, in which the word is generally used, to signify the withdrawing an irritation from an inflamed part by exciting an irritation in another. There is no known law in the economy which justifies us in supposing that such is ever the case, and if it were, the remedy would infallibly increase, instead of alleviating a disease consisting already in a state of minor irritation. But independently of all theory on the subject, what are the conclusions to be drawn from every-day experience? When the seat of the inflammation is one to which we can immediately apply our medicines, as in cynanche tonsillaris, gonorrhoea, ophthalmia, and skin diseases, are the most effective gargles, injections, collyria, &c., usually such as excite or such as depress? and are the other direct remedies to which we have recourse with the greatest benefit in deep-seated inflammations, such as heat, electricity, acupuncture, &c., of a stimulant or sedative character? Now, is it not absurd, when we see that direct remedies of inflammation are always such as to communicate, not withdraw irritation, to continue to presume that indirect remedies, or reputed revulsives, such as emetics, purgatives, diuretics, errhines, sialogogues, diaphoretics, and in particular epispastics, are such as to withdraw, not communicate it? They all obviously act in the same way, and the effect of each class of revulsives in bringing the action of the dilated capillaries of each organ up to the line of health will of course be great or inconsiderable in proportion as the specific character of the new irritation is well or ill-adapted to the specific irritability of these vessels, and as the sympathy which subsists between the organ to which the revulsive is applied and the seat of the primary irritation is intimate or the reverse."

I do not in the least mean to make a charge of plagiarism against Dr. Ross, who, I have no doubt, was quite unaware of having been preceded by Fletcher. But in justice to the memory of the latter, I bring this forward now, and I endeavoured to do so in the *Practitioner*, to which a very short article with the above and another extract were sent immediately after the appearance of Dr. Ross's paper. The editor of that periodical has, however, refused to insert it, for what reason I do not know; but it is to be hoped he will be able to justify his refusal, as I find since that he has also claimed the priority of the above theory when reviewing a former work by Dr. Ross.

I am, Sir, your obedient servant,

JOHN DRYSDALE, M.D.

Liverpool.

### ESTIMATION OF TOTAL NITROGEN IN URINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Although I did not intend to trespass on your valuable space again, and that I stated I had neither time nor inclination to pursue a chemical controversy on the determination of the actual amount of nitrogen in the urine, yet, as Professor Reynolds thinks my zeal for the merits of my countryman Dr. Davy was in excess of my discretion, you will, I am sure, pardon the use of my pen again, to give a *résumé* of the subject so as to allow competent judges to decide whether Professor Reynolds' process was in unison with its professed object; probably, had I not forgotten that Professor Reynolds was himself an authority (as a discoverer), I should have been more diffident with offering any remarks to a Nestor of Ureal

Science; but, having been in my early days a pupil in the late Professor Davy's laboratory, and knowing the many papers his son, Dr. Davy, had contributed to chemical science, published in different scientific journals, I felt that what Professor Reynolds states as a rough and ready method for the determination of nitrogen in the urine was just the method that superseded Professor Reynolds' process; and therefore I thought his paper on the subject as a quick and easy method for the practising physician was a work of supererogation. *Imprimis*, the process which Professor Reynolds has brought forward for the estimation of the nitrogenous contents of the urine as one that "was exceedingly simple and expeditious," and by which, as he stated, "we can easily and quickly determine, with very exact precision, the quantity of nitrogen removed by the kidneys," by his bringing it before the Surgical Society we may reasonably infer he considered it as applicable to the wants of the medical practitioner.

Considering that the proposed process fulfilled very imperfectly any of these ends, which were, as I conceive, fully attained by Dr. Davy's method, which I had employed for several years, I pointed out in my first letter on this subject in the *MEDICAL PRESS* some of the objections to Professor Reynolds' process—viz., that its first stage, in which the nitrogen of the urine was converted into ammonia by the adoption of Will and Varrantraf's well-known soda-lime process, had been recently shown by Seegan and Novak not to yield correct results as to the amount of nitrogen in different nitrogenous bodies, and I objected to the estimation of the ammonia so produced by the degree of colour imparted to Nessler's test for that substance, and that the details of the entire process could not be carried out with any degree of success except by one well skilled in chemical manipulation, and would be subject to the gravest errors, unless the most scrupulous care were paid to the different parts of the process, thus rendering it quite impracticable for the medical practitioner.

Professor Reynolds, as a reply to these objections, directs attention to a point in his preliminary treatment of the urine—viz., the addition to it of sulphuric acid before evaporation and combustion with soda-lime, and infers that I had exhibited a great want of chemical knowledge in not referring to this point, which I considered to be quite irrelevant, as it would, I maintain, add but little to the accuracy of the soda-lime process, and, as regards my objection to his method on account of its requiring a considerable amount of manipulative skill, in addition to its not furnishing correct results, he merely says: "I venture to think that this (process) is sufficiently convenient in practice, while it affords results which are but little, if at all, below the truth."

It would have been more satisfactory if Professor Reynolds had given a direct answer to the objections made against this process, and had stated the probable amount of time required to make a determination by it, and had given us the results of his analysis to show its accuracy.

In my second letter I pointed out that Professor Reynolds had passed over without comment the observed inaccuracy of the soda-lime process, on which his method of estimating the nitrogen of the urine was founded, and I still urged my objection to "the depth of the brown tint" produced by Nessler's test being taken as the means of estimating the amount of ammonia furnished in the first stage of his process, it being an unreliable method of quantitative analysis, which could only give results on which any dependence might be placed when obtained by those in the constant practice of such colour examinations.

In reply to my second letter Professor Reynolds at length admits "the fact (as he says) well-known to chemists, that the soda-lime process does not necessarily give the total nitrogen in organic bodies," but points to his "preliminary treatment of urine with sulphuric acid as being specially directed and sufficient to meet the difficulty;" but he offers no proof whatever that it does do so, though I am quite willing to admit that it may tend to fix any ammonia that may be present in the urine, and may aid in breaking up the organic matter; but there is no evidence to show what its action may be, under the circumstances, on the various nitrogenous constituents or matters that may exist in the urine; and I do not see how this "preliminary treatment," consisting as it does in the addition of "a drop of sulphuric acid" to the quantity of urine taken, and the evaporation of the urine "to a small pasty residue" in the form of combustion tube which Professor Reynolds suggests, could make so easy and expeditious such an organic analysis which, "under ordinary circumstances," as he states in his original communication, "can

only be made successfully by a person possessing some skill in one of the methods of organic analysis." But I would say it was rather injudicious of Professor Reynolds to base a method for the determination of nitrogen in the urine, which he recommended for the use of the medical profession, on a process that has recently been shown by several experimenters to be untrustworthy, and those who have endeavoured still to uphold its accuracy have shown that very great precautions are necessary to be taken that it may yield results approaching correctness, and two of these necessary conditions are not fulfilled in Dr. Reynolds process (first of which is), the most intimate mixture of the substance with the soda-lime, which obviously cannot be effected by mixing it with (as Professor Reynolds suggests) "the small pasty residue of the urine" after evaporation in the combustion tube; and then, after such imperfect admixture, he directs that "a strong heat" be applied to the mixture. Now, it has been shown that one of the great sources of error in the soda-lime process is the application of too strong a heat during the combustion, as it occasions the loss of ammonia by decomposing more or less of that substance.

Now, as regards what I have termed Dr. Davy's simple and beautiful method (the utility of which I have so upheld in this correspondence), Professor Reynolds, to prove that the assertion he made respecting its inaccuracy in a former letter was well founded, refers in his last to the *Chemical News* of June 12, 1874, where will be found a notice of the proceedings of the Chemical Society of London of the 4th ultimo, at which Dr. Russel and Mr. West brought forward a simple method of estimating urea in urine which might be employed in the wards of an hospital, the reaction attendant on which usually occupies, as they state, about ten minutes, and which, being merely a modification of Dr. Davy's original process, using hypobromite instead of hypochlorite of soda, and a rather complicated apparatus instead of his simple graduated tube, tends, in my opinion, to establish its value.

These gentlemen, however, state that in using this modification "it is found that the amount of nitrogen given off from a given weight of urea is about 8 per cent. less than the theoretical, but by a curious coincidence the corrections which would have to be made for the reduction in the volume of the gas for aqueous vapour and a temperature of 65° F. compensate for this," so that this source of apparent error, according to their observations, is practically of little moment.

Professor Reynolds, however, with what seems to be a want of fairness, has dwelt on the 8 per cent. of loss observed by these gentlemen, whilst he has taken no notice of their further results, which show that such loss, if it really exists, is compensated for. But be this as it may, as regards Mr. West and Dr. Russel's modification, I find, on referring to Dr. Davy's original paper on the estimation of urea, that the amount of gas obtained from a given weight of that substance differed only by a few thousandths of a part of a cubic inch from the calculated quantity that should be furnished, being a difference so small that it might be practically disregarded, and fairly attributed to the unavoidable sources of error that appertain to almost all analytical operations. I also find that there exists a very close agreement between the results which Dr. Davy obtained in some comparative estimations he made of urea in different samples of urine, employing Liebig's and his own method, which also shows its accuracy. But, if further proof be thought necessary as to this point, I may refer to the "Handbook for the Physiological Laboratory," a work published last year, in which Dr. Lauder Brunton, one of the authors of that treatise, in speaking of Dr. Davy's method, says, at page 551: "The writer can vouch, from personal observations, of the great accuracy of this method where applied to solutions of pure urea, and believes that if carried out with the apparatus devised by Dr. Hüfner for the determination of urea by solutions of alkaline hyperbromites, it would prove the most useful and reliable method for the determination of urea."

I have now concluded my *résumé*, as well as replied to Professor Reynolds' last remarks, and trust my review has been an impartial one, although Professor Reynolds, having admitted the inaccuracy of the soda-lime process, the basis on which his test has been founded, I might have offered that as a sufficient reply to any objections made against Dr. Davy's test, which, resting as it does on the unerring laws of chemical science, cannot be subverted by any hypothetical idea (however plausible), and as I do not intend again to recur to the subject, I leave to those conversant with chemical subjects to decide how far Professor Reynolds' experiments have tended

to the advancement of chemical science or the edification of the members of the Surgical Society, and to remind him that the didactic style of writing is better suited for the school-room than for the members of a learned profession.

Apologising, Mr. Editor, for such a trespass on your space,  
I am, your obedient servant,

R. AUSTIN, M.D., Medical Analyst.

5 Cullenswood Terrace, Ranelagh.

[We cannot see that the controversy need be further extended, Dr. Reynolds' right to reply being, of course, conceded.—Ed. M. P. & C.]

## REFORM OF EXAMINATION IN THE IRISH COLLEGE OF SURGEONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The remarks made at the General Medical Council will, it is to be hoped, be of service in directing the attention of the Irish College to amending the method of examination, though we must admit the language used was in no measure authorised by the report of the visitors, who did not insinuate that the mode of examination was purposely intended to allow inferior candidates into the surgical arena of practice, but that the detail of carrying out the testings might be improved; this has been admittedly a "bone of contention" with the Council of the College for a considerable time, I believe as far back as 1870. Various reasons have retarded the application of the revised system, which would have been open to none of the objections made by your late correspondent. Timidity and procrastination seem principally to have influenced, while outside interests were put in motion to upset the coach of reform. Now, Sir, while the verdict returned to the Irish College of Surgeons was passed by a jury and judge of those opposed in interests and nationalities, there are suggestions besides those which might be taken as a "slap" at the Irish, which deserve the consideration of the profession. They were well given in a London leader last week.

- 1st. The permanence of class examinations by the various professors, and the certifying of their being satisfactorily attended.
- 2nd. That the area of examination on the secondary professional subjects of botany, zoology, chemistry, and materia medica should be limited and defined.
- 3rd. The presence of two examiners, or of one and an assessor at each clinical and oral examination.
- 4th. That the examination on any subject should not be conducted either wholly or in part by the teacher of the candidate on that subject.

Now, Sir, these seem reasonable recommendations; they have often been alluded to before, and on various occasions, and something should now be done. As stated in a recent issue, the most glaring impropriety is the last. It is not easy to know what the impression on the public would be if it were generally known; but I have seen even on the list of those to attend the examinations at the Irish College the names of private teachers, or "grinders," who might attend the examinations of even their own private pupils, and who are supposed by students to have the power of influencing the result of the examination. This certainly does not look well.

It is time now that action should be taken, and in the right direction, in rendering the examinations at the College as perfect as can be, and a model for others. When that is attained, surely the Medical Council must insist on the enforcement of a uniform testing throughout the three kingdoms.

Yours faithfully,  
F.R.C.S.I.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having been from home, I did not see the *PRESS* and *CIRCULAR* for two weeks. When I did, I was not surprised at the indignant reclamations which I found on the subject of the Examinations of the Royal College of Surgeons and the attack made on them by Sir Wm. Gull.

I feel quite satisfied that improvement in the examinations is

still required, and trust they will be made. I have long felt disgusted with the self-glorification of too many of my *confrères* in the College, who repeat the stories of the past, as if the same state of things existed as in the olden time, when the examination of the Royal College of Surgeons of Ireland was really in advance of most other institutions. Credit has not been given to other corporations for the improvements they have made, and we have not made progress even *pari passu*. I trust the hint will now be taken, and that the Council will do its duty in insisting on improved examinations, and getting rid of all obstructives, if such exist, as is hinted, amongst the examiners.

At the same time, I do not think that the pettish onslaught of Sir Wm. Gull was deserved, and take comfort in the knowledge that though highly esteemed for deep research in all the practice and science of the profession, Sir Wm. Gull is not so highly revered for the possession of good common sense. His escapade in connection with the post-mortem of the Emperor is not forgotten, and is a good gauge of the calibre of his mind in that essential qualification of full manhood: we need not, therefore, be too sensitive to his testy and ill-considered attack.

Let the Council proceed steadily in the path of reform. Let the examination be honest, searching, and calculated to discover the amount of the candidate's knowledge—not the extent of his ignorance. Above all, let it be practical, and not crotchety. Let "*fiat justitia*" be the motto of the examiners, and I have no doubt that we may still heartily exclaim "*Floreat Collegium Chirurgorum Dublini*," despite the nasty or ill-tempered criticism of any man who in his self-esteem may think that his word can make or mar.

I am, Sir,

Your obedient servant,

July 31, 1874.

F.R.C.S.I.

### CROUP.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you or any of the readers of the MEDICAL PRESS AND CIRCULAR kindly inform me what is the probable earliest age for an infant to suffer from croup? I do not mean the spasmodic form of the disease; I allude to the true inflammatory kind, tracheitis. I have been always under the impression that from eighteen months till seven years was the usual period of life for the malady to show itself. I believe this is also the opinion of most physicians. After an experience of many years I *never met* in my practice the disease commencing *before the time above-named, or later than the age of nine*.

Lately, however, a medical friend informed me that in his opinion the disease may take place at any age, and that it is not uncommon even before six months old. I do not deny that such a thing may happen, but it is so rare that one, according to my idea, might say it never occurs at all. To elicit the opinion of other members of the profession on the subject I shall feel obliged by your giving insertion to this letter.

I remain, your obedient servant,

July 17, 1874.

L.K. & Q.C.P.

## Medical News.

Royal College of Physicians of London.—The following gentleman was admitted a Fellow of the College on July 30th:—

Druitt, Robert, Lancaster Street.

And the following gentlemen were elected members by ballot:—

Robinson, Frederick, M.D. St. And., Lupus Street.  
Liveing, Edward, M.D. Camb., Queen Anne Street.  
Blake, Charles Paget, M.D. Edin., Torquay.  
Carter, Thomas Albert, M.D. Edin., Leamington.  
Goodridge, Henry Frederick Augustus, M.D. Lond., Bath.  
Robertson, William Tindal, M.D. Edin., Nottingham.  
Gervie, Henry, M.D. Lond., St. Thomas Street.  
Crucknell, Henry Heanes, M.B. Oxon., Welbeck Street.  
Moore, William Whithers, M.D. Edin., Brighton.

Thorowgood, John Charles, M.D. Lond., Walbeck Street.  
Smith, Eustace, M.B. Lond., George Street, Hanover Square.

Lee, Robert James, M.B. Camb., Savile Row.

Green, Thomas Henry, M.D. Lond., Wimpole Street.

Bradbury, John Buckley, M.D. Camb., Cambridge.

The following gentlemen on the same day were admitted Members of the College:—

Barlow, Thos., M.B. Lond., Great Ormond Street.

Blanc, Henry, M.D. Montpellier, Rue de la Paix, Paris.

Donkin, Horatio Bryan, M.B. Oxon., Devonshire Street.

Edmunds, James, M.D. St. And., Savile Row.

Roper, George, M.D. Aberd., West Street.

Also at the same time the following gentlemen were admitted as Licentiates:—

Boase, William Francis Fookes, London Hospital.

Clarkson, John Wilkins, Surbiton.

Fyffe, Benjamin, Arundel Hotel, Arundel Street.

Gould, Alfred Pearce, University College Hospital.

Keates, William Cooper, Dulwich.

Lea, Julian Augustus, Charing Cross Hospital.

Leacock, Charles George, Colebrook Row.

Lloyd, Morgan, Guy's Hospital.

Mavor, William Samuel, Mountfield, St. Leonards.

Mawson, William Arthur, Dispensary, York.

Moir, Gerald Chetwynd Algernon, St. Mary's Hospital.

Newby, Charles Henry, Mecklenburgh Street.

Park, John Steele, Claremont Square.

Pyburn, George Wilkinson, University College Hospital.

Roe, Edward, St. Bartholomew's Hospital.

Seccombe, George Samuel, Bellefield Road.

Sturmer, Arthur James, Percy Circus.

Vawdrey, Theophilus Glascott, Kent Villas, Upper Lewisham Road.

Woods, David, St. Peterburg Place.

Royal College of Surgeons of England.—The following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College on July 24th, 27th, 28th, and 29th:—

Abbott, Charles Edward, Liverpool.

Armstrong, Henry G., L.S.A., Staines, Middlesex.

Badcock, John Henry, Abingdon.

Bathe, Henry Hearsey, Southampton.

Benton, Samuel, Southend.

Bernays, Sidney Adolphus, Brixton Hill.

Boulter, Harold Baxter, Hull.

Bromley, John Maddern, New Swindon.

**The Czar's Bounty.**—The Lord Mayor has distributed the sum of £500 left with him for public charity by the Emperor of Russia, after his Imperial Majesty's visit to the City, as follows:—The Metropolitan Free Hospital, £100; the London Hospital, £50; the Dreadnought (Seamen) Hospital, £50; the Poplar Hospital, £50; the Shipwrecked Fishermen and Mariners' Society, £40; the City of London Truss Society, £25; the Society of Friends of Foreigners in Distress, £25; the Surgical Aid Society, £25; the Seamen's Chapel, £20; the Royal Alfred Aged Institution, £25; the Goulston Square Baths, £25; the City Dispensary, £20; the Finsbury Dispensary, £20; and the Victoria Hospital, £25. His Majesty the Emperor has sent to Colonel Fraser, C.B., the Commissioner of the City Police, a valuable ring, as a souvenir of his memorable visit.

**Royal College of Physicians of London.**—The following officers have been elected for the ensuing year:—Censors: Dr. Herbert Davies, Dr. J. W. Ogle, Dr. Habershon, and Dr. Garrod.—Treasurer: Dr. F. J. Farre.—Registrar: Dr. Pitman.—Harveian Librarian: Dr. Munk.—Examiners: (Anatomy and Physiology) Dr. George Harley, Dr. Church; (Chemistry, Materia Medica, and Practical Pharmacy) Dr. Thomas Stevenson, Dr. John Harley; (Medical Anatomy and the Principles and Practice of Medicine) Dr. A. W. Barclay, Dr. Sibson; (Midwifery and the Diseases peculiar to Women) Dr. John Clarke, Dr. Braxton Hicks; (Surgical Anatomy and the Principles and Practice of Surgery) Mr. Jonathan Hutchinson, Mr. G. D. Pollock.—Curators of the Museum: Dr. F. J. Farre, Dr. Peacock, Dr. W. Wegg, and Dr. Sibson.

**British Association for the Advancement of Science.**—The forty-fourth annual meeting of the British Association will commence at Belfast on Wednesday, August 19th, and extend over the following eight days. At the first meeting of the General Committee the President for the year will be elected, and the place of meeting for 1876 resolved upon. In the evening of Wednesday the proceedings proper will open with the annual address by Professor Tyndall, on assuming the Presidency. On Thursday evening there will be the usual *soirée*, and on Friday night a discourse will be delivered by Sir John Lubbock. The Saturday, as usual, will be devoted to excursions. On Tuesday there will be another *soirée*, and on Wednesday the meeting will be brought to a close. The sectional meetings will be held as usual. In mathematical and physical science Professor Jellett will preside; in chemical science Professor A. Crum Brown; in geology Professor Hull; in biology Professor Redfern; in geography Major Wilson; and in chemical science Professor Thomson will preside.

**The Apothecaries Act Amendment Act, 1874.**—We have received the following abstract of the "Apothecaries Act Amendment Act, 1874," of which we have already spoken:—

"The first section enacts that the Act shall be cited as the 'Apothecaries Act Amendment Act, 1874.'"

"The second section repeals those provisions of the Apothecaries Act of 1815 which require any member of the Court of Examiners (or any of the five apothecaries to be appointed under that Act for examining assistants to apothecaries) to be a member of the Society of not less than ten years' standing."

"The same section repeals those provisions of the Act of 1815 which require candidates for examination for a certificate to practise as an apothecary to have served an apprenticeship of five years."

"The third section enables the Society, with the sanction of the Privy Council, to form part of any Conjoint Examining Board to be constituted under the provisions of the Medical Act of 1858."

"The fourth section provides for the Society having power in certain cases to strike licentiates off their list."

"The fifth section saves any existing rights of women to be admitted to the examination of the Society."

Independent of the power given to the Society to form part of any Conjoint Examining Board, the Act will, therefore, be found to effect the following important changes:—1. The Society can for the future select their examiners from the whole medical profession or from any scientific body, instead of (as formerly) from a very limited class of the members of the Society. 2. Apprenticeship is no longer made a necessary condition required of candidates presenting themselves for examination for a certificate to practise as an apothecary. 3. The Society can strike licentiates off their list on the same grounds as they can be struck off from the Medical Register. It may be observed, in conclusion, that no new rights are conferred upon women by the fifth section of the Act.

**Adulteration of Food Act.**—In the House of Commons on Thursday, in answer to Sir H. Peek, Mr. Solater-Booth said that since his hon. friend and also the hon. member for the City of London had, with a large and influential deputation, waited upon him at the Local Government Office, requesting that the Government would take steps to suspend the operation of the law with regard to prosecutions under the Adulteration of Food Act, he had consulted his right hon. friend the Home Secretary, who confirmed the opinion he had himself expressed to the deputation, that it would be quite impossible for the Government to interfere in any way with the execution of the law on this subject, and that they were not prepared to bring in a Suspensory Bill. But, at the same time, having regard to the result of the very full inquiry that had been instituted by a select committee, the Government hoped that the prosecuting authorities would be very careful in taking proceedings under the Act, especially with regard to tea, as to which so much difficulty and some injustice had arisen. Great care would be taken that no further recommendations were made as to the appointment of analysts until the subject had been considered by Parliament.

## NOTICES TO CORRESPONDENTS.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Dr. C. B.—The MS. to hand. The paging is now consecutive.

SIR JAMES PAGET AND THE "PICTORIAL WORLD."—Referring to the illustration in the *Pictorial World* of the lecture delivered at St. Bartholomew's Hospital, which we noticed in our last, Sir James Paget has written to say that the illustration is much against his wish, as he instantly and positively refused to allow the artist to take any sketches when asked. In defiance of this an abstract of his lecture appeared with the illustration, and Sir James Paget wishes it to be distinctly understood by the profession that he highly disapproves of the course adopted by the *Pictorial World*, with which he is not unnaturally indignant.

OPHTHALMOLOGY EXTRAORDINARY.—Mr. Ede, of Birchfield Road, Birmingham, inventor of "Ede's Patent American Eye Liquid," which cures cataract, aged sight, near sight, and every disease to which our optics are liable, has addressed a note to our publisher asking terms for fifty-two insertions of his advertisement. We make Mr. Ede a present of this, and advise him to send for terms to those newspapers which are always greedy of quick advertisements. Our readers are not supposed to see quite so many newspapers as we, and they will probably be surprised to hear that long and expensive advertisements are going the round of the Press of this "American Eye Liquid," for which it is claimed to cure the most distressing diseases of the eye, the removal of cataract included. Yet so it is; and the public are gulled into the belief that because a list of testimonials is appended, including two from amiable old gentlemen of 84 summers, who for years had been unable to find their own doors, but from the use of this "Patent Eye Fluid," price 2s. 9d. per bottle—large bottles, 11s., they can see it o thread the smallest needle—it is all "as true as the Gospel," and seize the tempting offers with avidity. Truly, this is an age of enlightenment; what will the next be?

A CORRESPONDENT has sent us the following announcement, which is being distributed broadcast:—"A new method of curing diseases of the eye, including certain forms of (we would add mental) blindness, without operation, by Dr. E. Pomies, M.D., oculist, from Paris, 81 Euston Square, London. N.B.—The doctor has room for one or two patients to reside in his house." We hope he will always have room, and plenty of it.

Here is a curiosity that may amuse for a moment:—

**"PANDEMIC OBSERVATIONS."**

To the Editor of the MEDICAL PRESS AND CIRCULAR.

I have the honour to send you, dear Sir, as the result of my earnest observations, the following remarks, requesting you to publish them in your journal in the interest of public welfare and a general discussion.

Yours truly,

CHARLES OF GUNTHER,  
Apothecary.

Munich, July, 1874.

**Pandemic Observations.**—The only rational and surely efficacious preservative for human beings in those acute diseases, which must be reduced to a sick blood (as cholera morbus, pest, yellow fever), consists of a mixture of substances after the following prescription:—

R. Natri phenylic, Kali oxychloric, Kali hypermanganici aa partes aequales, Sulphuris crudi partes decem. Misceantur exactissime. Pulvis servetur in vitro bene clauso.

To be taken every morning a knife's point full, with a little rum or arrack.

Every one who makes use of this remedy during epidemic diseases, will certainly be exempted from them.

To render this remedy accessible to everyone without any expense must be the task of governments, of medical and philanthropic clubs.

The reasons which induce the undersigned to the before-maintained assertion are briefly developed in his pamphlet, "Observations in judging Contagious Diseases," and we will give in the following lines the most important excerpt:—

1. The diseases before mentioned are principally based on a deficient supply of oxygen gas to the blood.

2. In case of illness the organism is highly supported in its resistance by an immediate and internal use of nitrous-oxyd gas (laughing-gas) in its gaseous or absorbed condition.

3. Only the prophylactic impregnation of the body with antiseptic remedies and rich in oxygen gas preserves from contagion and hinders thus the best from farther propagation.

4. Till a complete and rationally executed canalisation of all places, in which an abundance of population is prevailing, the establishment of apparatuses, by which oxygen gas may be produced in the lodgings of the poor, in the hospitals and public buildings must be wished for.

5. Prises must be set out by the government in order to find out the simplest and cheapest methods of producing the oxygen gas.

6. Self-production of saltpetre on the surface of the earth, in the lodgings, on the walls—viz., the conditions of it, must be removed and prevented.

CHARLES OF GUNTHER, Apothecary.

**GEORGE H. PORTER, F.R.C.S.I.**; M.Ch. T.C.D. (Hon. Caus.), Surgeon in Ordinary to Her Majesty the Queen in Ireland; Fellow and Ex-President, R.C.S.I.; Senior Surgeon to the Meath Hospital.

Obstetric Physician:  
**JOHN CRONYN, M.D., F.R.C.S.**, Examiner in Midwifery, Roy. Col. Surgeons; Ex-Assistant Physician Rotunda Hospital.

Work, Income, and Expenditure for Twelve Months, ending June 30, 1873.

Annual number of Dispensary patients	...	...	...	729
Number of visits paid by such patients	...	...	...	5,847
Number of patients within the Infirmary	...	...	...	124
Number of operations performed	...	...	...	168
Total gross expenditure per bed per annum	...	...	...	£27 15 0
Average expenditure per intern patient	...	...	...	1 10 6

The Infirmary is wholly dependent on private benefactions, and is in debt to the Medical Officer. SUBSCRIPTIONS ARE EARNESTLY REQUESTED

**THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.**

PATRON:—H.R.H. THE PRINCE OF WALES.

This Institution was founded in 1839, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office.

40 MOLESWORTH STREET, DUBLIN.  
 W. O'NEILL, Secretary.

**SAINT MARY'S COLLEGE, CONWAY, N. WALES.**

Conducted by Oxford and Cambridge University Men,  
 A qualified Surgeon being a Resident Master.

The Course of Instruction comprises the Greek, Latin, French, and German languages; Classical Composition, English Grammar and Composition, Geography, Ancient and Modern History, Writing, Arithmetic, Mapping, Book-keeping, Algebra, Mathematics, Mensuration and Land Surveying, Drawing, Natural Science, and Music. Lectures are periodically delivered by the Principal on Natural Philosophy, Chemistry, and Astronomy, accompanied by illustrations and experiments.

**TERMS:—**

£40 per Annum under 13 years.  
 £50 over 13

These Terms include the whole Course of Instruction; but brothers are received at a considerable reduction.

**HOURS:**

8 to 11, and 1.30 to 3.30. Preparations from 4 to 5.30. Dinner at 6, after which the boys go out under the care of a master for a ramble on the mountain or for a stroll on the sea shore. Pupils who are able to swim go, under the immediate care of the Head Master, for bathing at 11.15.

As a recreation, pupils are instructed (their Parents consenting) in Drilling (by a Commissioned Officer in the Army, who is also a Master in the College), Swimming, Rowing, Boxing, Fencing, Dancing, Single Stick, Gymnastics, and all the other requisites of a Gentleman's education—Riding and Driving alone being extras. There is also a Reading-room in the house, supplied with the principal daily and weekly papers, for the use of the Pupils. Great attention is paid to the morals and the manners of the Pupils. Corporal punishment is not allowed under any shape or form.

Monthly Reports of conduct and progress are sent to the Parents, and a Monthly Holiday is given by the Head Master to those Pupils only who have given satisfaction during the month.

The Michaelmas Term will begin on the 1st September; Lent Term, 1st February; and Easter Term on May 1st.

No notice is required before the removal of a Pupil, and boys may enter at any time, charge only being made for the part of the Term during which they have been present. Fees for one Term to be payable in advance—the balance in case of removal will be returned.

Applications for admission to be made to J. R. KENNEDYBELL, Esq., 9A Sackville Street, London, W.

Established 1848.

**PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.**

50 LINCOLN'S INN FIELDS, W.C.

**J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,**

&c. (KING'S COLL.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

**PRACTICES AND PARTNERSHIPS NOW OPEN** for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

**Y 995. MIDLAND.** In a pleasant town, containing about 10,000 inhabitants, an OLD-ESTABLISHED PRACTICE, realising about £950 a year. Only one opponent. Appointments yield over £200 a year. No gentleman with less than £750 at his immediate command need apply.

**Y 920.** In a pleasant part of the Eastern Counties, an EASILY-WORKED PRACTICE, yielding £400 a year. Advancing age the cause of retirement. There is great scope for increase, and no practical opposition. Population about 3,600. The house and premises are very convenient, and centrally situate; they can be rented at £45 a year, or sold for £500. Premium for the Practice £350, part of which may be paid by instalments.

**Y 959. MIDLAND. FIRST-CLASS COUNTRY PRACTICE,** including the best families in the district, with prospects of great increase. Average receipts, £400 a year. Midwifery, £1 1s. to £5 5s. Visits, 3s. 6d. to 10s. 6d. The best society can be had, and great opportunities for field sports. The work is exceedingly light, and the connection suited for a gentleman of means desiring pleasant occupation, the professional work being over by one o'clock in the day. Very little opposition. The longest journeys are under five miles. The residence is large and commodious, fitted with modern conveniences, stabling for eight horses, large garden, green-house, &c. Five acres of land. The whole may be purchased or taken on lease. Premium for the Goodwill of the Practice one and a half years' purchase.

**Y 994.** Twenty-four miles from London, a TRANSFERABLE PRACTICE and APPOINTMENTS FOR SALE. Appointments, £170. Private Practice, £150, but capable of great increase. No opposition. Good house, garden, lawn, and green-house. Rent, £21. Premium, £250.

**Y 992. COUNTRY PRACTICE** in a Picturesque District. Receipts upwards of £400. Appointments, £276. There is great scope for increase. Excellent house, with stabling, &c. Rent, £38. Premium, £250.

**Y 996.** Excellent opportunity for introduction to a WEST-END PRACTICE. An experienced gentleman who has been practising in the suburbs of London is about to remove into the neighbourhood of the best squares. He desires to secure a Partner to take charge of his suburban Practice, and ultimately to share his West End connection. No gentleman without £400 at present command need reply.

**Y 997.** In a large town, an OLD-ESTABLISHED PRACTICE for TRANSFER, with partnership introduction or otherwise, as may be desired. Average receipts for the last three years are upwards of £1,500. Midwifery fees £1 1s. to £3 3s. Appointments bring in about £350 a year. Patients good middle-class.

### REPORT ON SYPHILIS.

By C. R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.,  
Senior Physician to the Metropolitan Free Hospital.

DR. FOURNIER'S LECTURES ON TERTIARY SYPHILIS.

(Continued from page 89.)

In a lecture on tertiary syphilitic affections of the velum palati (*Le Mouvement Méd.*, 27th June) the able lecturer thus continues:—

The tertiary lesions of the velum palati, to which I shall join as natural annex those of the tonsils, will occupy us in this lecture.

If the interest of a disease be measured either by its frequency, or by the gravity of the accidents it may occasion, or the efficacy of the assistance which art may afford, no disease merits more in this triple point of view an attentive study than that we are about to study.

On the one hand, tertiary lesions of the velum palati are extremely common, so common that in our wards we have them always, and you will meet them pretty frequently in the wards of hospitals not specially devoted to venereal diseases. On the other hand, there may result from the localisations of tertiary syphilis on the velum palati a double persistent disease, which, although not compromising life, is for all that grave, since it compromises in a most serious fashion two very essential functions—deglutition and phonation; and, finally, there are few affections where art is more powerful than in this to prevent or cure serious lesions. There are few cases where the physician may be, as here, more exposed to allow grave and irreparable lesions to appear, if he mistake the disease and does not know how to remedy it in time; or, on the other hand, when he is more powerful to ward off urgent danger and to offer to his patient the most efficacious assistance.

Tertiary lesions of the velum palati and tonsils do not

at all differ, nosologically and historically, from the tertiary lesions of other mucous membranes, not more than tertiary cutaneous lesions do.

Here again, as in the other mucous membranes of the mouth, we shall meet with lesions of various kinds, which are exactly those we have already studied on the tongue.

These lesions are naturally divided into two groups—

1. *Ulcerating Syphilitic Affections*, in which the ulcer constitutes the essential clinical phenomenon, and the first of all, in which at least the ulcer does not succeed after the melting of a tumour originally solid.

2. *Gummy Tumours*, consisting, as all gummy lesions do, in diseased products originally solid, which, later, soften and ulcerate the integuments.

#### I. ULCERATING SYPHILITIC AFFECTIONS.

This first group of lesions has only a secondary importance relatively to that we shall describe further on under the name of gummata of the velum. On the one hand, in fact, it is formed by lesions rather rare. Without being positively uncommon, tertiary ulcers of the velum palati are, however, infrequent, less frequent assuredly than those of the lip, the tongue, or genital mucous membrane.

On the other hand, these lesions do not present in this place any character which calls attention to them. They are here what they are elsewhere, i.e., always, ulcerations, or affections of the mucous membrane, rather variable in their objective appearances, more or less extended, most commonly comparable in diameter to a piece of 20 or 50 centimes, rarely larger; we see some, however, which measure two or three centimetres in length, and one in breadth, or even a centimetre and a-half, or two centimetres; these ulcers are more or less hollowed out, attack the velum in different cases to an unequal depth; most frequently, however, superficial, and with more or less raised edges, generally rounded or oval, presenting a yellowish, or yellowish-grey base, sometimes carpeted with adherent pellicles, whitish, opaline, or even pseudo-membranous.

Without being themselves truly painful, these lesions determine, because of the functions devolving on the organs they attack, a notable annoyance, which is marked

by habitual sensibility of the throat, with dryness and difficulty of mastication, and especially of deglutition. The food is felt in the mouth; whether acid, spiced, or hot, it becomes painful. Besides, the presence of these ulcers in the mouth excites a disagreeable salivation, calls forth frequent desire of swallowing, which only make the pain worse—keep up, in a word, a permanent condition of distress, and of difficulty in the fauces. Sometimes, however, these lesions are completely indolent, and may even be ignored by the patient.

A fact we must not forget is that ulcers of this kind are not seated solely at the anterior aspect of the palate. They have been seen to attack the posterior aspect of the velum; there, it is easily understood, they escape observation, and can only be shown to exist by rhinoscopic examination.

Ulcerative syphilitic affections of the tonsils are far more frequent. Here, again, there are few distinctive characters in the ulcer, which appears under the aspect of an irregular wound, even because of the position it occupies, generally greyish, or yellowish-grey, sometimes pul-taceous, hollowed, or cupped, more or less extensive; sometimes partial; sometimes covering the whole surface of the tonsil; sometimes almost indolent, sometimes awakening a certain reaction near it (swelling and redness); and then being accompanied by pain in deglutition, continual annoyance in the throat, with sometimes buzzing and painful dartings in the ear. In some cases the tonsil has been attacked, and even completely destroyed by ulcers of this kind.

#### II. GUMMY TUMOURS OF THE VELUM.

This much being said about the first group of these tertiary lesions, let us come to the most important subject which is to occupy us to-day—gummy tumours of the velum.

Gummy tumours are not different in the velum palati from what they are elsewhere. They consist originally in a solid neoplasm, which softens later on, opens, and finally degenerates into an ulceration of the mucous membrane.

But the conditions of its position affix to it a peculiar aspect, and determine especially special lesions which it is important to examine in detail.

Let us, then, follow the gummy tumour in the different periods of its evolution, and see to what phenomena it gives rise at each period.

I. The gummy tumour quite at its commencement consists in a little solid tumour, hard, without inflammation, raising up the mucous membrane, and nearly resembling what a foreign body would do (such as the kernel of a cherry or an almond) introduced into the velum, between the two mucous surfaces. Its form and volume at this date are comparable either to a small pea (in which case the tumour is spheroidal) or to an almond.

But it is extremely rare to observe the gummy tumours at this initial period. It is a rare fortune to observe the gummy tumour arising in the form of isolated tumour, circumscribed, cold, and without inflammation. It is not, certainly, once in thirty or forty times that we meet it in this embryo period.

And why? Because one of two things occurs: either the gummy tumour passes unremarked by the patient at this period—the patients do not even perceive it, for it awakens neither pain nor functional annoyance of any kind; or perhaps the patients observe that they have a little tumour in the palate, a little kernel; but as the tumour is quite indolent and not annoying, they do not disquiet themselves, thinking that it will go away of itself, and don't come to consult us.

Thus, usually, it is most frequently at an epoch far later on that we commence to observe in practice the gummy tumour of the velum, at an epoch when it is extended, developed, and where it has commenced to awaken in the neighbouring tissues a certain degree of inflammatory reaction.

Well, then, let us examine the gummy tumour at this moment, the earliest moment when we are asked to look at it.

II. What do we find at that period? One or other of the two following appearances:—

1. Either (this is the rarer case) there is a circumscribed swelling, and of inflammatory aspect, occupying some portion of the velum. On a point the size of a piece of 50 centimes, or a franc, there is a notable projection on the velum of the form of the segment of a sphere. At this level the mucous membrane is red, visibly inflamed, tense, glistening, varnished, and resistant to the touch. It is evident that this projection corresponds to an infiltration of the velum, and that the foreign substance has reached in an inflammatory way to the neighbouring tissues.

2. Or, again, what is far more common, there is diffused inflammation of a more or less extended portion of the velum; a fourth part, a third, or a half of the velum is the seat of this infiltration; more rarely the velum is affected more extensively, in its two-thirds, or three-fourths. Almost never the velum is entirely affected.

Another clinical attribute which the eye notices at first sight, and which the touch confirms, is the thickened condition of the velum.

This projecting velum, projecting at one part, ought of necessity to be thickened. The eye guesses this thickening, and the touch confirms it. The finger, moved alternatively over the healthy and diseased parts, gives the sensation at the level of these last of notable thickening. The thickness is triple, or quadruple.

Besides, the same exploration teaches that at the level of the diseased parts the velum is hard and resistant. And, again, the last phenomenon remarked, which is but a consequence of the preceding, this velum, which is partially engorged, has become partially rigid and fixed. I will explain.

When you examine a healthy velum you see it during your exploration execute certain motions, under the influence of the respiration, or its own proper influences; you notice it rise, fall, and become modified in its form in the convex portion, in its pillars, and other parts. Nothing like this now occurs. The velum infiltrated by the gummy syphilitic affection is motionless, if not wholly, at least partially, in the extent occupied by the infiltration; it is not susceptible of those delicate movements it executes when sound; it is rigid, as if fixed down and inert.

And yet this velum, pray remark, is not the seat of a distinct, isolated, and localisable tumour; it is itself which is affected in its proper tissue and swollen.

I insist on this point, because it is of great importance. The majority of students to whom we show such a lesion generally called gummy tumour expect to see something else, and say to you, "Where is, then, the tumour? You speak to me of a tumour, and I do not see it. I only see a velum palati thicker than usual—a swollen velum, hard and red." Well, gentlemen, in fact, what is called gummy tumour has disappeared, probably by consecutive infiltration of the neighbouring parts, or by surrounding inflammatory engorgement. I cannot tell you how, but it has disappeared as far as a distinct tumour, and what we notice now is nothing more than a swollen velum, thickened, and itself constituting a tumour, or being itself the tumour.

To sum up then: Deformity of the palatine arch; thickening of the velum; hardness; rigidity in the movements, in which the attacked part does not participate, dusky redness of the parts, all without distinct tumour.

Such are the objective symptoms; it is by the same, then, that you ought to recognise the gummy tumour of the velum.

Now, are these correlative functional troubles added to these objective symptoms? This, gentlemen, it is important to discuss, on the one hand to dissipate certain errors repeated by pathologists on the point, and on the other hand, to establish one of the most salient sides of the lesion we are speaking of, that is, its peculiar insidious character.

It has been said, and you will see it repeated even in certain recent monographs, that these lesions were accompanied or preceded by general phenomena—certain premonitory malaise, excessive fatigue, weariness, headache, fever, want

of appetite, furred tongue, &c. . . Here, gentlemen, I protest. This is an error of observation, a material one.

On the one hand, the gummy tumour is not preceded, or announced, by any general trouble. On the other, it is evolved absolutely without heat, without reaction on the organism, without fever, or without any disturbance of the health.

That in certain cases, of which I shall speak further on, in those cases of lupus of the throat where multiple lesions take on an excessively acute progress, there is produced a rather marked general disturbance of the health, characterised by a febrile state and by malaise, want of appetite and weakness, &c.; this may be true, and is sometimes seen. But that apropos of a simple gummy tumour of the velum, or a circumscribed and solitary lesion, as is most frequently observed, nine times in ten there are produced phenomena of this kind is quite false, and the proper character, on the contrary, of the lesion we are at present studying, is to arise in a cold and latent manner with a kind of absolute indifference of the organism.

And, not only is the lesion produced without any general symptom; it, moreover, is locally evolved, at the time, at any rate, of which we speak, with remarkably slight symptoms. This is even a symptom which it is very essential to place in evidence, and on which I cannot too strongly insist. Do you think that this lesion which just now is about to end in such important lesion, which is about to perforate the palate, determines, when it arises, symptoms proportionate to its real gravity? Not at all.

This lesion, quite on the contrary, is remarkably inoffensive, singularly benign, far more benign than the slightest inflammatory angina. First of all, it is very slightly painful; I might almost say it is not painful. The palatine gummy tumour, when it is forming, or softening, does not give rise to acute suffering, no beating, nor stabbing pain, nor constriction of the fauces.

All that it produces is a certain annoyance in the throat, a sore throat slight enough to make the patients not disquieted in general.

In the second place, there are few functional troubles: the voice is scarcely modified, or at most, as it is in a slight angina; deglutition somewhat impeded, especially in the ingestion of liquids; and only occasionally, nasal regurgitation of drinks on account of the rigid state of the velum. Even this is rather rare, and only noticed in the cases where the velum is complicated to a great extent.

And that is all. Nothing more is felt.

So much is this the case in the majority of instances, that the patients do not even disquiet themselves about these slight phenomena. They only pay a divided attention to them. They think themselves affected with a common sore throat, accidental, as every one has experienced twenty times in his life, and which is easily cured without treatment. They attribute the general malaise to cold; in short, they suffer so little from it, and feel so little troubled that they do not even think of consulting a doctor, and await with tranquillity a cure which, according to their belief, cannot be delayed.

Listen to them, indeed, relating their misadventure, when later, terrified at the destruction which has taken place so unexpectedly, they hasten to us. It is invariably the same theme, the same stereotyped phrase, "How could I have expected this? I was in good health, and had not the slightest fever. Indeed, I was not suffering from sore throat, I felt almost nothing, I thought I had taken cold, and that was all. I have had ten times sore throats which have given me more pain, and which got well of their own accord. How could I have been able to think myself threatened with what has since happened?" &c.

In fact, gentlemen, there exists a singular opposition, an almost extraordinary contrast between this absence or this benignity of local troubles, and the results in which the disease ends suddenly at the time of which we are speaking. The slightest angina, the slightest quinsy, would make a hundred times the disturbance, and end in nothing grave, and be cured without any result. The

palatine gummy tumour, on the contrary, benign and almost latent, conducts to serious and irremediable lesions of which I am about at once to speak to you.

The palatine gummy tumour is then, *par excellence*, insidious, remember that, gentlemen, for that is the most essential character of it, and the most striking feature of the disease, that which it is most important to be acquainted with. It is a lesion which commences and constitutes itself with the most innocent appearances, but which all at once ends in grave accidents which I must speak of. These accidents are those of the tertiary period, the period of ulceration, the study of which we are now about to enter upon.

III. After having persisted a certain time in the preceding form, the palatine gummy tumour undergoes the lot of all gummy tumours, that is, it softens and opens at a point, and then it ulcerates. There are phenomena of the tertiary period which we must study in detail.

First of all, how does the gummy tumour open? Almost always without the knowledge of the patient, sometimes during mastication, sometimes in sleep, as in one of our patients who, having gone to sleep with slight sore throat, from which she had suffered some days, was not a little stupefied in awakening on the morrow "with a hole in her palate," no longer speaking without a nasal twang, and rejecting drinks by the nostrils.

In all cases, this opening of the gummy tumour always takes place painlessly; then the opening which occurs enlarges almost immediately. In a very short time it is converted into a true ulceration, which extends more or less in a remarkably rapid way, progressively attacking the whole extent of the parts infiltrated by the gummy tumour.

There is nothing surprising in the rapid progress of the ulceration which then takes place. This rapid destruction was prepared. It is not, indeed, a healthy mucous membrane which thus disappears in a few days; it is a mucous membrane long diseased, undermined, thinned, and almost destroyed already when perforation takes place.

One of two things then occurs: the velum, in spite of its thinness, nevertheless remains without perforation; or again (and this is far the most frequent event), the velum is destroyed in all its thickness, and if this destruction is directed to its central parts, it is perforated in various points.

In the first case, where there only exists a simple ulcer, without perforation, what we remark is very simple: there is loss of substance, a sieve-like appearance in the velum, the anterior aspect of which is more or less hollowed out, but the posterior aspect remains intact. It is, in a word, an ulcer, the base of which is formed by the portion of the velum which remains healthy, reminding us of the aspect and all the characters of the gummy ulcer, *i.e.*, ulcerations with sharply-cut edges and red border, resting on hard, engorged, and elastic tissues, of yellowish base and sloughy, that is, with base formed by degenerated gummy tissue in the state of slough.

Sometimes this ulceration (especially if suitably and rapidly treated at this moment) remains as it is, without extending itself and without burrowing more; then it becomes repaired and scarred over.

In this case, the most lucky, the velum palati has remained imperforate. But more frequently, after having destroyed the anterior part of the velum, the ulcer finishes its work, and, attacking the posterior part, finishes by complete perforation. The affection then enters into the second order of lesion, about which we are going to speak in a moment.

Let us at once say, not to have to return upon this point, that the opening and ulceration of the gummy tumour do not always take place, as we have supposed until now, at the anterior aspect of the velum. In the great majority of cases it is, indeed, at the anterior aspect that the tumour appears and opens. But in some cases the opening takes place behind. Nothing is changed in the diseased process on that account. Only the perforation, in place of taking place from before backwards, as in the preceding case, and

the most ordinary one, takes place in the opposite direction, i.e., from behind forwards.

In the second order of cases the velum is attacked in all its thickness. It is then not alone a superficial affection that we notice on the velum, it is an attack without any base, a complete destruction. Now, according to the point where it takes place, this destruction of the whole thickness gives a different aspect to the lesion. If it take place on the sides of the palate it simply ulcerates the velum. If it operates on the central parts, it makes a complete hole in the velum, a perforation proper.

But it is of little consequence whether the destruction take place here or there with respect to the intrinsic characters of the lesions, which always remain the same and present themselves always with the same objective attributes. Whether the gummy ulcer be marginal or central, it none the less preserves its proper characters; and these characters are never else than those of all gummy tumours, i.e., hollow ulcer, sharply cut, resting on violet-red tissues, hard, elastic, as if lardaceous, with yellowish base and sloughy, or again, often covered with a sort of whitish varnish, pellicular in form (the aspect assumed indeed pretty frequently by all specific ulcerations of the throat).

Only the disposition of the gummy ulcer differs according to the points it occupies. If it occupy the periphery of the velum, it consists in an ulcerating band which borders the palate and more or less ulcerates it, penetrating more or less towards the central parts. If it occupy the central parts it then constitutes a sort of ulcerative canal hollowed out in the velum; this canal does not measure less than six or eight millimetres through the thickness of the velum, sometimes even more, about a centimetre.

The ulcerated walls of this canal are hollowed out of a tissue which is hard, red, violet-coloured, and which is but the velum infiltrated with special or inflammatory products. They present a yellowish, diphtheritic surface, or aspect identical with that of the gummy ulcer.

In ulterior evolution this ulceration is considerable, by extension within certain limits; it extends over the whole surface of the parts infiltrated by the neoplasm, but not further. All that has been attacked by the gummy tumour is eaten away and disappears; but when that is gone, the ulcerative process ceases, and does not go further (I make reservation, however, for certain cases of which I will hereafter speak, and in which the ulceration continues beyond the initial seat of the gummy tumour, assuming a phagedænic aspect).

Here a curious remark must be made. When the ulcerated tissues disappear, how do they disappear? Without leaving any trace, and without the knowledge of the patient or practitioner. What becomes of them, we know not, nor do we see. They appear to melt away, as we may say. In every case they form no distinct slough which separates from the healthy parts and falls into the mouth; we shall find no traces of them; this is a fact which we may explain as we will. These tissues disappear as the lung disappears when excavated in an extent which is often considerable by cavities from tubercles. Probably, and even certainly, I may say, there takes place then a kind of molecular destruction, of which the elements, of small size, divided, dissociated, are taken away by the saliva, ejected with the sputum, or swallowed.

And finally, when this work of destruction has been ended, what remains of the diseased parts? what is the condition of these parts?

Too briefly, persons are contented to say in general that the velum is attacked, perforated, and destroyed. These matters, it seems to me, deserve closer examination, and different kinds of mutilation of the velum may be distinguished. These forms are four in number, and may be designated in the following way:—

1. *Marginal Ulceration of the Velum.*—Here the mutilation attacks the periphery and margin of the velum, the pillars, and the uvula. These are attacked and destroyed for more or less an extent. For instance: On this woman, the right arch of the velum has been ulcerated

to the extent of half a centimetre, from before backwards, and for about two centimetres transversally. When the gummy infiltration comes near the uvula, at its base for instance, this appendix may be detached; we see in this way the uvula, guillotined by the gummy ulcer, detached wholly from the velum. At other times, and more frequently, the uvula, attacked by the infiltration, is destroyed molecularly, and disappears, without leaving any trace. The velum then remains, deprived of this appendage.

2. *Perforation.*—This mutilation of the velum consists in a hole dug in the area of the velum amidst the parts which remain healthy. It may occupy various positions—the middle line, the lateral part, the anterior or the posterior parts. When seated on the posterior part of the velum it becomes almost marginal, and is then merely separated from the posterior border by a very narrow band of healthy tissue, reduced to some millimetres of antero-posterior thickness. Most frequently the form of the perforation is rounded, and that more or less regularly; sometimes perfectly round, as if made by a compass; at other times oval; or more lengthened, elliptical, and then always lengthened transversally, in the path where the muscular tractions of the velum act. The dimensions vary; sometimes the perforation is small, so that the point of a stylet can scarcely penetrate it; more frequently it has a more considerable diameter, and allows easily the passage of a sound of ordinary dimensions; at other times (and that is not rare) it has the dimensions of a piece of 50 centimes; more rarely it attains the size of the kernel of an apricot. It may be even larger. I have seen one recently which measured three centimetres transversally and a centimetre to a centimetre and a half in antero-posterior diameter.

3. *Division into Curtains.*—This form is almost as frequent as the simple perforation. It is produced by the following mechanism: when the gummy infiltration has occupied a certain extent from before backwards of the median portion of the velum, this portion is destroyed finally by softening and ulceration. But, when the work of destruction has been accomplished, the velum is found divided in its middle line from before backwards, and segmented into two lateral flaps. What happens then? Under the influence of the muscular retraction, these two flaps separate like large curtains of a window tucked up. Adhering to the hard palate by their apex, they separate laterally by their inferior part, and simulate pretty closely, I repeat, window curtains, which, approaching in their upper part, diverge laterally below. When, in this kind of mutilation, the uvula has been left, we see it hanging to the flap to which it has remained adherent, and forming there a sort of soft and movable appendage, or test.

4. *Destruction almost Total, or Complete Destruction.*—This last variety is much less frequently noticed. Yet it is not very rare that a proportional destruction of the velum succeeds to these gummy infiltrations where very extensive, when the velum is mutilated more or less completely. Let us further remark this: were it mutilated only partially, it would appear to be so much more because of the lateral traction of the stump remaining. Most frequently the pillars remain intact, at least partially, but retracted towards the lateral parts of the pharynx, and confounded with them, they appear to have vanished.

Let us finally say that in certain cases, luckily rare, the destruction is complete and absolute; then there remains not a trace of the velum.

Dr. Nevins Hyde, Lecturer on Syphilis and Dermatology in Chicago (*Chicago Med. Journ.*, July, 1874), quotes Dr. Brouardel concerning those lesions of syphilis, which are apt to prove fatal. Dr. Brouardel (*Gaz. des Hôp.*, April 14) thinks that the graver forms of syphilis occur when treatment has not combated the disease.

Precocious malignant syphilitic skin diseases are developed in the aged, the scrofulous, and those with diatheses. Ricord used to say there was a scrofulate of syphilis. Disorders of the lungs in syphilis simulate phthisis.

Tertiary syphilis of the brain, liver, and heart, are to be considered carefully. Periostosis of the cranium, rare on the external table, are frequent on the internal table. Their seat of predilection in the vicinity of the sella turcica, the basilar apophysis, and base of the brain.

The encephalon exhibits gummy tumours developed at the expense of the brain substance, and lying on the convolutions, the crura, or the pons varolii.

Violent nocturnal headache, producing sleeplessness, vertigo, and vomiting are common to all syphilitic periods, but the tertiary forms are the most persistent. The iodide of potassium is not of itself sufficient for a cure. Mercury is also needed.

Most cases of paralysis of the third nerve are not dependent on osteal or periosteal lesions, as they come after secondary disease. Epileptiform seizures are less complete and more localised when syphilitic than when uncomplicated. There is in general no *aura*, nor is there alternate pallor and suffusion of face.

*The Liver.*—Interstitial hepatitis and gummy tumours of the liver strangle the vessels, &c., and produce atrophy and amyloid degeneration of the gland. This causes ascites and jaundice. Syphilitic ascites is variable—re-appearing and disappearing. It is therefore more curable in extreme than in other forms. The jaundice may produce an almost black discolouration of surface. Hæmorrhage from the stomach, bowels, and nostrils may accompany it.

*Larynx.*—Edema may originate in mucous patches of vocal cords or adjacent membrane. Thence may result ulcers invading the trachea, and aphonia from destruction or ulceration of the vocal cords, and stenosis.

## MEDICAL SCIENCE AND MEDICAL TEACHING.

By GEORGE BARRACLOUGH, M.A. (Cantab.), M.R.C.S.

(Continued from page 108.)

If we conceive, as I presume we do, that study of the structures and organic functions of the lower classes of beings in their healthy state is likely to enlighten us in respect to similar things in the human frame, why should we not conceive the same to hold good in regard to what is morbid, so far as it exists in lower forms, and act accordingly? And, yet, has this hitherto been our plan? These are the considerations which induce me to think that in respect to the physiology of health and disease we are not in the right path of research. We have commenced our researches at the wrong end of the series. Otherwise, when we ponder on the poor results achieved, as contrasted with the circumstance that the libraries of our medical schools are literally groaning under the vast accumulation of recorded facts, the only supposition open to us, by way of explaining the barrenness of this ant-like industry, is, that the medical profession is wholly devoid of genius—a thing hard to believe.

As involving λόγος, and therefore the highest theoretical and teleological considerations, it is difficult to see what the pure empiricist, or positivist has to do with physiology or pathology. Physiocracy, necroscopy, are the proper terms for him—æsthetics, not logical science. And yet he persists in retaining within his vocabulary, and desecrating thereby, a word about which cluster the grandest associations of ancient thought. Indeed, to our poor humiliated λόγος, how well the lines apply that the laureate sings of another desecration:—

"The grand old name \* \*  
Defam'd by every charlatan  
And soiled with all ignoble use."

In the physioscopy (not physiology) of morbid structures, what the empiricist or thorough-going positivist has to note are simply the phenomena which are present to the senses. And it must go very hard with him to find a

language appropriate to his negations, or his positivisms. To be consistent, he must reject not only scientific, but popular nomenclature. As pointing to feeling and consciousness, rather than to any physical state, the term "dis-ease" will hardly suit his purpose, and still less will the popular phraseology as exhibited in the expressions *maladie*, the French *maladie*, and in such ordinary phrases as "My liver is bad," "My lungs are bad," "My leg is bad," implying the recognition of a right and wrong in Nature, not in any ethical sense, but in the sense of fitness, meaning, purpose, design, means to an end—teleology, in fact. And these are all ideas abhorrent to the positivist's principles, or, rather, to his negation of principles.

I know not how it may be with others, but it seems to me that I never yet heard the conversation, nor saw the book which could for long avoid the manifestation of ideas implying a recognition of efficiency and finality, notwithstanding all protestations to the contrary. For instance, Dr. Wilks, though he discards all such ideas as are conveyed in the terms "conservative processes," and the "vis medicatrix nature," and evidently writes as a disciple of Comte when he remarks, "Such notions would show that we had not reached the true scientific method, but, according to Comte, were still in the metaphysical stage of thought, when external agencies were supposed to be ruling the world;" yet, notwithstanding this rejection, he details a case in which he accepts the doctrines associated with the above phrases in the most unhesitating manner, and guides his treatment by them accordingly. A case of ulceration and perforation of the appendix cæci is instanced, in which the lymph that is thrown out around the aperture may, by "glueing the opening to a neighbouring part of intestine, prevent further egress of faecal matter, and limit the inflammation to a corner of the abdomen. Absolute rest, therefore, is necessary." And "Nature," the learned doctor goes on to remark, "attempts this by temporarily paralysing the movements of the intestine, and taking away all desire for food." Here the paralysis of the bowel and stomach is regarded as a conservative process, and as the manifestation of a certain *vis medicatrix nature* behind, or inherent in the phenomena, and by the agency of which a cure is to be wrought. Those abstract entities, viz, the "forces" of that other abstract entity "Nature" (all of them, here, objectively misrealised), which later on are described as going "blindly" on, heedless of results, are not here blind and heedless, but "half-intelligent powers with benevolent objects in view." Here we have teleology, theory, and I know not what other dreadful things of the kind, all very different from that positivism and empiricism which the learned doctor elsewhere holds up to our admiring gaze. I may add, by the way, that more than one or two of the cases adduced by Dr. Wilks, as well from his own practice as from that of others, as illustrations of successful empiricism, savour much more of theory than of empiricism. At the same time, I may just call attention to the fact of consumptive persons being characterised as "over-bred," because this appears to involve an ideal, i.e., a metaphysical standard of breeding.

The approving reference to Comtes' philosophy, which we have just seen, illustrates still further what I have before remarked, that the real question at issue between Dr. Wilks and others is not one merely of the usage of truly scientific method, but of what constitutes such a method, or, in our author's case, what he conceives to constitute a truly scientific method. It does not seem to have occurred to him that other physicians, standing on their equal rights in regard to the conception of method, might decline to accept as "truly scientific" the method which M. Comte founded on his famous negations. It is not at all my purpose to defend any particular theories which may be associated with the expressions "conservative process," "vis medicatrix," "force," "Nature," vague terms, as Dr. Wilks designates them; but I do protest against Dr. Wilks' assumption that the notions associated

with these terms do, in the minds of many who use them, necessarily imply the existence of agencies external both to the mind and phenomena, and at work behind these latter. As we have seen, Dr. Wilks himself cannot get on without some of these vague terms, and it is he, rather than those whom he censures, that uses these terms to represent something clothed with transcendental and noumenal existence—something, by way of efficiency, at work behind phenomena. Such are the entities which he associates, for instance, with the terms disease and Nature. And this is the very proceeding, substituting "objectively realised" for "personified," which is condemned by M. Comte, when, in the famous "Exposition," he describes the notions resulting from it as "*Véritables entités (abstractions personifiées) inhérentes aux divers êtres du monde, et conquies, comme capables d'engendrer par elles-mêmes tous les phénomènes observés dont l'explication consiste alors à assigner pour chacun l'entité correspondante.*" The terms under consideration denote, with many who use them, simply general conceptions of the mind, in the way of hypothesis, theory, law. But then there is no attempt, and quite the reverse of any desire, to misrealise these by projecting them beyond the mind or conceiving of them as entities having an independent objective existence, external both to the mind and phenomena, and determining the existence of these latter by virtue of some native efficiency. No reasonable person imagines that any higher reality can be conferred upon these conceptions by transporting them into the phantomland of Noumena. For us, *τὸ νοητὸν* must take the place of *τὸ αἰσθητὸν*, though without being at variance with it, and therefore is rightly regarded as having the higher reality. Such, then, being the nature of the notions associated by most scientific minds with certain "vague terms," the reproach that such notions are understood as implying the existence of noumenal entities does not apply to them, but to those who, like Dr. Wilks, misrealise their mental conceptions.

It is not a little remarkable that our author should object to the use of certain abstract terms because they imply the existence of metaphysical entities, for the ontological speculations which he associates with certain terms imply the existence of transcendental entities which have ever been denominated metaphysical by the historians of mental science. It is equally remarkable that he should, as he evidently does, expect this objection to have any weight with those to whom the greatest claim that any entity can have to be considered real resides in the possibility of applying to it the term metaphysical in another of its recognised acceptations, as denoting right conceptions—"notiones rectæ," not "temeræ abstractæ." Such persons do not feel themselves constrained to abandon all effort after right conceptions, right theories, simply because there happen to be wrong ones; and this sort of entity has, for them, a reality amply sufficient, because, when the result of the right conception, it involves more than could ever be "actually" obtained through sense, and which, therefore, has the higher reality. For this reason, they do not consider the case demands the exchange of a sufficient reality, for one whose existence is only warranted by the belief and alleged intuition, not of their own, but of another mind.

In regard to what is said about the forces of Nature going "blindly on, heedless of results," such truly scientific doctrine might consort very well with positivism did not that philosophy express the greatest repugnance for such "*véritables entités*" as "force" and "Nature." The proper form of expression for pure positivism would be, "the physical facts of the universe succeed each other without reference to any final or efficient cause." But however the doctrine may stand in reference to positivism, the language will not harmonise with doctrine deemed truly scientific by those who think they have the privilege of seeing, in respect to organology and the physiology of animals, a design, meaning, purpose, fitness to an end in the individual organs. Such persons,

though not excluding the notion of cause as historical, yet do not rest in this, but go on to a fuller conception of causation. With them the "reason" why a thing exists is something more than the sum of all its physical antecedents. The efficient cause of the simple existence of anything in space is spirit, that being the only transcendental noumenon they recognise for the sake of efficiency; and the efficient cause of its existing as an event in time or portion of a series is the circumstance of its being the expression of a thought of the Demiurgus, and a means to accomplish the end designed by him from the beginning. Hence, it would be impossible for such persons to speak of the forces of Nature, according to their conception of them, as going blindly on, heedless of results, for such language would involve a contradiction in terms. I know not how far such language would be acceptable even to those whose conception of cause does not transcend the historical view. Finally, they who indulge in teleological speculations aver that they find them eminently serviceable in suggesting right theory and conception, and consequently, as highly valuable in truly scientific investigations; and, indeed, the history of scientific discovery abundantly confirms their doctrine.

There now only remains for examination Dr. Wilks' "Theory or Canon of Criticism;" and this is neither the least interesting nor the least important of the subjects about which he has expressed his views. In the dogmatic form into which the learned doctor has thrown his remarks on this subject he gives utterance to a piece of pure egotism, which, independently of its suggesting what is true or false—as being undisguised and as giving an insight into his views of phenomena and knowledge, need not encounter our disapproval, did he not, in affirming it, transgress his own canon. I must crave the permission of the reader to cite entire that portion of the paragraph in which the canon of criticism is disclosed, as follows:—"All truly scientific theories are completely disassociated from the mind of him who has framed them. Man is the 'interpreter of Nature,' and thus, in taking the works of a great philosopher, like Faraday, little of the individual is to be seen. The purer the work and the more of Nature in it, the less is the will of man seen. In very many of our medical theories I witness exactly the reverse: the framer of them is intimately associated with them, and with him they sink or fall. I have more than once inwardly condemned a scientific work because the prominent object before the reader's eye has been the author, and my conviction has always been confirmed by the experience of time. I believe this to be a true canon of criticism, and therefore no argument in favour of any particular method of treatment of disease, framed by the fancy, can have any weight with me. And a very large number of our plans are of this kind."

"Man is the interpreter of Nature;" but let us try to penetrate the vague generalities implied in this Baconian phraseology, and endeavour to clear our eyes a little of the dust it is so often effective in throwing into them. Every individual man engaged in investigating the physical facts of the universe does, by means of his powers of abstraction and generalisation, institute comparisons and find relations between phenomena; further, by the aid of imagination, theorises and evolves principle and law: and in this consists the interpretation of Nature. The use of the abstract term "man" has the effect of concealing the individuality and personality at work in the above process; as if, not individual men, but some abstract entity, or "man in the abstract" more engaged in scrutinising, not actual physical facts in the first instance, but an abstract though objective entity—viz., Nature. We cannot help wishing these two entities—much joy of the process; but to persons who are not positivists with a surreptitious liking for such things, they are rather deficient in interest. When the learned doctor goes on to remark, "the purer the work, and the more of Nature in it, the less is the will of man seen," we ask ourselves what is meant by "more of Nature in it." It is tolerably clear, from the context, that our author is here regarding Nature as a realised abstraction; for if Nature means only physi-

cal fact, then, the more numerous the facts interpreted, the wider must be the interpretation, and the more numerous, consequently, must be the processes of *personal* thought it involves. That these personal processes are not all of them seen is a mere matter of form. Is it always an advantage, we further ask, that "little of the individual is seen?" In all science that is not mathematical there must invariably be a strong egotistical element: it may be concealed with infinite art, it may be frank and ingenuous, or it may be abstruse and empty, and the science of which it is the vehicle correspondingly empty; but, still, exist it must. It is the diffident and modest manifestation of this personal element, both in its history, *i.e.*, how it has come to be what it is scientifically, as well as in its final form—rather than the mock-modest hiding of it under a bushel—that is of such inestimable value instructively to those that are to come after. Bacon was sensible of this when he wrote:—"Whereas knowledge, which is delivered to others as a web to be further wove, should if possible be introduced into the mind of another in the manner it was first procured; and this may be done in knowledge acquired by induction; but for that anticipated and hasty knowledge we have at present it is not easy for the possessor to say by what road he came by it. Yet in a greater or less degree anyone might review his knowledge, trace back the steps of his own thoughts, consent afresh, and thus transplant his knowledge into the mind of another as it grew up in his own. . . . He who would promote the growth of the sciences should be less solicitous about the trunk or body of them, and lend his care to preserve the roots, and draw them out with little earth about them." One other testimony I may add to this, from the pages of the late Professor Grote, who, after affirming that his own writings are full of egotism, remarks of other authors to this effect: "I can only say that in reading what others have written it is a matter continually occurring to me, how much better it would have been if they had been more egotistic; how much better we should understand what they meant if they had described the manner in which the thing had come to present itself to their mind, and let us a little see their thought in the forming; also, how many pages of literary history, ending at last in unsatisfactory result, would have been also saved if this had been the case."

(To be continued.)

### CASE OF TWIN-BIRTH—COMPOUND PRESENTATION OF SECOND CHILD.

By J. P. BYRNE, M.R.C.S.E., &c., Anghrim, Co. Wicklow.

As I believe compound presentations are of rare occurrence, I venture to place the following case before the readers of the MEDICAL PRESS, which, although it illustrates nothing new in midwifery, may possess sufficient interest from the fact that it belongs to a class of presentations not generally observed in practice. Of these presentations Churchill says (*vide* p. 438): "In the cases recorded by Drs. Joa. Clarke, Collins, and Johnson, no example is mentioned, and in those of Mesdames Lachapelle and Boivin, only three, *i.e.*, three cases in 75,903 deliveries." Ramsbotham, speaking of similar cases, observes (*vide* p. 367): "The feet, a hand, and the breech are not very infrequently detected together at the pelvic brim, and I have known some few instances in which the head, a foot, and a hand were all presenting at the same time. If it were practicable under such a complication, it would be most advisable to push the hand and foot above the brim (as will be hereafter more particularly advised), and allow the head to come down alone; if not, to turn the child by traction at the foot and bring down the breech."

Early on the morning of the 23rd June I was called to attend a woman in labour. She had given birth to a child, but was said to be in need of my services "as all matters

had not come right." I of course concluded it was a case of retained placenta, and merely took a bottle of *ergotæ liq.*, as is my usual practice in such cases—of frequent occurrence in my locality. On my way to her house (one mile and a half distant) I was met by two messengers at different intervals, who told me the woman could not be worse, and that I could scarcely reach her alive. On my arrival I found a very different case from what I anticipated: the poor woman was suffering the most agonising pains, which were unfortunately unavailing, owing to the impaction in a malposition of a second *fœtus*. On examination I found a hand, two feet, and funis presenting well beyond the external parts, and so doubled was the *fœtus* that the head was close to the perinæum. The midwife in attendance (a person whose knowledge of obstetrics was merely traditional, and whose faith in the powers of Nature so unlimited as to approach to fatalism) had no idea of the nature of the case till she was appalled by the appearance of the extremities, and hence I found myself devoid of instrumental means, should such become necessary. I had first to deliberate briefly what was to be done, then to act. The uterine contractions were frequent and violent; there was no time to be lost. The cord was pulseless, so that I entertained no doubt as to the death of the *fœtus*. I had a case of complete impaction to deal with. I thought of "spontaneous evolution" as useless to expect; craniotomy, and the danger of waiting for instruments. Pressing the head upwards, or making traction on the feet produced no movement in the position of the *fœtus*. By a few patient efforts I succeeded in returning the arm within the pelvis. Still the *fœtus* continued immovable. It then occurred to me to try and return the legs, which I did separately, and with less difficulty than might be conceived. No sooner were the legs returned than the head came forward with a rapidity suggestive of spontaneous expulsion, and the delivery was completed.

Using expression on the uterine tumour for a few moments brought away the placenta, which were of large size, and so intimately fused together as to present all the appearances of a single structure, whether viewed from the uterine or opposite aspect; they contained separate membranes and cords; there was no hæmorrhage or untoward symptom; the children were well formed, and of average size, having regard to gender (female) and plurality of birth. The first child did well. Although my patient was rather a delicate woman, I was not called on to see her afterwards, but have been informed she made an excellent recovery.

### INDIAN MEDICAL NOTES—No. XXII.

(FROM OUR SPECIAL CORRESPONDENT.)

SIMLA, July, 1874.

#### TOPOGRAPHY OF MEERUT.

UNFORTUNATELY, it is only by dribblets, spasmodically from books, individuals, and personal observation, medical events and facts are gleaned concerning Meerut, instead of being found cut and dry. Yet, what becomes of all the reports? where are all the Blue Books? where is all the dearly bought experience of the past to warn and teach those who come after? English books are very expensive—for instance, Murchison, thirty-two shillings—are heavy to carry, if spared by the damp, the ants, or the rats; and as medical officers are daily liable to be *ubique quo fas et gloria ducunt*, or rather, wherever required, it is impossible to keep more than travelling necessities, as before remarked. With this apology, the water of Meerut may thus be described: Total hardness, 12; mineral matters, 14.35; total solids, 16.25; lime estimated as carbonate 7.5; chlorine, estimated as chloride of sodium, 1.6; sulphuric acid, estimated as sulphate of soda, 2.3; alkaline carbonates, estimated as carbonate of

soda, '95. Every chemical examiner praises the water. Covered wells, pumps, the purchase of land, to the exclusion of natives and their habitations, figure amongst the stereotyped suggestions. Down some wells sentimental lovers urinate together, by way of soul communion, and formerly it was said in Oude that water hardened the soldiers, as Damascus tempered their sword-blades. Up at certain elevations, where various fevers through a variety of causes are sometimes welcomed, the contamination of water appears neutralised by the splendid air. In 1866, at a school of 67 boys, 17 in the month of July were attacked by enteric fever, a master also affected, yet not a single death. The ages ranged from 5 to 24, the average 14; those who had been there three years escaped; fever ranged from 14 to 45 days, the average 29; maximum temperature 103°; pulse 148, often feeble, jerky, or dichrotous; eruption out on 15th day; generally noticed on 10 boys: abdominal tenderness, 15; tympanitis, 14; gurgling, 10; mostly in right iliac fossa, headache, 11; delirium, 7; epistaxis, 5; deafness, 4; diarrhoea, 14. Dr. Clarke found mercurials, quinine, and chlorate of potash useless, but acetate of lead, turpentine, good air, judicious diet, castor-oil (in eleven instances), were valuable remedies. Wine and brandy only required in two cases. The air of the Himalayas is the finest in the world, as will be discovered gradually by invalids who can afford to leave home, provided the remedy is not deferred too late. A phthisical lady who could not live in England is here wonderfully healthy and strong, at least, she was waltzing vigorously last night, and promised her pleasant company to join our riding party this afternoon. Lord Elgin and Sir Sydney Cotton were opposed to very lofty elevations, as strongly as Sir Charles Napier was in favour of Mean Meer. Lord Dalhousie, Lord and Lady Canning, amongst many others, contracted disease in the Plains; so did poor Dr. Beatson, who was buried here last week. At his funeral, besides the Simla Volunteers, a mountain battery of artillery attended—the guns, wheels, carriage, ammunition, carried by various mules—everything perfect, and should the opportunity occur of medically describing Simla, this system of warfare will be discussed. Lord Elgin, who sleeps on the heights of Dhurmsala, beneath the snow-clad pinnacles where, according to native tradition, the Creator and the angels dwell, found the keen mountain air too much for his enfeebled heart. So do others. I am attending a very bright little lady, who complains of fatigue, smothering, want of sleep; but what with diet, beef-juice, quinine, iron, and strychnine, judicious exercise, clothing, change of house, she will soon be right, and forget her consumptive history. Sir Sydney Cotton was in favour of Cheratt, 3000 feet: bring the men down on elephants; nothing like marches, drills, camps of exercise, temporary barracks, gardens, cricket, plenty of officers living amidst the men, gymnastics, road-making. Reckless of the sun, averse to coddling soldiers, he pointed out how easy it was to snip a telegraphic wire, or to tear up railway sleepers, and that "instant action" must ever be the motto. Instant action is required in times of pestilence, to have tents, carriage, provisions, and stores ready to fly and to keep running until the plague is shaken off and this brings me back to continue the account of Meerut as furnished to the Royal Commission by Dr. Wilkie and others.

On the 21st of May, 1860, the diseases of this then favourite, popular, and healthy station, included intermittent, remittent, and continued fevers, acute and chronic dysentery, bilious and spasmodic cholera, distinct and confluent small-pox, acute and chronic rheumatism. Hogs rare, dust abundant, elevation above the nearest water, four miles distant, about 110 feet; no rice or indigo cultivated near; water found at 18 feet in dry weather, and 16 feet depth during the rains; extent of tank surface about 2,229,397 feet about the station, which was built originally on new ground. The native city, about two miles distant, the bazaars, and the gaol appear to have had their share of sickness. The 6th Dragoon Guards, the 35th, and a native infantry regiment, all enjoyed better health than at

other stations, no part of the cantonment sicklier than another. The subsoil water question does not appear to have been ventilated to any extent; at present, throughout the district, as (I think) before mentioned, thanks to canals, from 18 feet to 8 feet has the water level risen, a water-logged soil, in fact, conducive to paludal fevers.

The burial ground north of the station, 400 yards from any barrack (prevailing winds westerly), area, 56,000 square yards, sandy subsoil; each grave 2½ feet wide, 4½ feet deep, separated 2½ feet if of earth never reopened; those of brick, occasionally, to admit a second tenant. Years ago I wrote a note about the disposal of the dead, and I think now, as then, in favour of shallow graves planted with shrubs of rapid growth and greedy roots. Cannot the botanist help us? Our poor native doctor was burnt the other day; and during the mutiny certain ladies were thus transformed dust to dust, ashes to ashes. According to evidence, the sick-list here from August to October ran heavy, and from March to May variola or measles appeared; scurvy or guinea-worm rare. Calculated roughly, the percentage of hospital admissions to total admissions ran—fevers, 56·00, dysentery, 2·75, cholera, 0·09, variola the same, rheumatism, 3·24; whilst the percentage of deaths to total deaths recorded—fevers, 25·00, dysentery, 24, cholera, 0·04, variola, 0·08, rheumatism, 0·04. Venereal cases were about 8 per cent to total admissions.

The amusements and means of instruction consisted only of balls, courts, skittle-grounds, a theatre, and schools; and how the men confined to barracks from 8 a.m. to 4·30 p.m. passed the time is not stated. The amount of drunkenness is apparently small.

The barracks, then accommodating 800 artillery, two regiments of cavalry, two regiments of infantry, Queen's and native troops evenly divided, included about 4,227 men, in 705 rooms, built in 1810, 1819—indeed, gradually on to 1854, 1858, 1859. *Bedsteads*, wooden frames laced with tape or cane; *mattress*, quilted cotton; *lavatories*, one per company; also two plunge-baths per regiment; *privies and urinals* drained into cesspools, the contents of the former received into copper pans and removed by filth-carts daily; these cesspools distant from the wells 670 feet, from the barracks 60 feet, were 4½ feet in diameter by 40 feet deep, and periodically cleansed by opening the tops and bucketing out the contents. *Drainage* conducted by wide open masonry drains to a tank 1,700 feet from the barracks, also to a nullah 5,000 feet distant. The bazaars had self-supporting latrines, each tenant responsible for the cleanliness of house and surroundings; also the two slaughter-houses were constantly inspected. The *stables*, consisting of sheds supported on pillars, were 100 yards from the barracks, and 800 from the hospital; no dung-heaps.

At the *canteen* each man on payment could have two drams *per diem*, at noon and sunset, else a pint of beer and a dram of rum. For more than a quart bottle of country liquor leaving the premises the publican required a pass.

*Rations*.—Bread, 1 lb., beef or mutton, 1 lb.; rice, 4 oz.; sugar, 1 3-4th oz.; black tea, 5-7th oz.; or coffee, 1 3-7th oz.; salt, 1 oz.; split firewood, 8 lbs.; vegetables, 1 lb.; the stoppage about fivepence, the cost one shilling.

*Duties*.—Drills in cold weather up to 10 a.m., and after 4 p.m. about an hour or a little longer; in hot weather before 6 and after 5; about fourteen nights in bed.

Dr. Wilkie, the principal medical officer, after stating the healthy indications of sugar-cane, the objections to black soil, clay, and kunkur, expressed his views: Soldiers at 22 landing ready drilled in the cold weather should at once, by marching, bullock, train, or boats, be sent to their regiments; should serve in India 12 years, and if invalided, not to embark later than February. Acclimatisation on the Hills was not considered feasible; the dews and fogs, the chills of night and morning, the dangers of the sun, aggravated by intemperance, figure amongst other hints. The barracks built of bricks set in lime mortar, the roofs supported on timber trusses and

covered with thatching, grass, or tiles; the floors of stone, brick on edge, or brick flat with concrete terracing over, generally raised 2 feet above the ground, no passage of air underneath; ventilated by doors, windows, and roof apertures, verandahs on both sides—one for messing, another for recreation—lighted with oil-lamps at night. The dimensions of certain rooms were as follows:—

Barrack Rooms.	Regulation number of men in each.	Length.	Breadth.	Height.	Cubic contents.	Cubic feet per man.	Superficial area of floor sq' ft.
<i>Rum go down.</i>							
8 centre wards...	90	215	30	20	129,000	1,400	71
4 side .....	45	215	10	20	43,000	955	47
Other barracks...	74	205	22	20½	119,515	1,615	60 70-74
Booket lines...	72	198	24	20	96,040	1,320	66
4 rooms .....	1	18	114	20	4,050	..	202
Camel shed boks.	68	201	27	14	75,973	1,117	79

Infantry .....	16	50	24	26	30,000	1,875	75
Married barracks	1	18	11	22½	4,555	4,555	188
Guard room .....	14	49	18	17	30,980	220	122
Cavalry hospital	104	298	25	20	149,250	1,435 10-104	71 78-104
Artillery .....	100	295	25	22	162,250	1,622	73
Infantry .....	180	454½	25	15½	168,388	1,052	67
Infantry d'tched	64	174	25	15½	67,435	1,053	168

A guard room is only occupied by a few.

Let us now turn to a very compact report of the cholera in 1861 in Northern India, a work published in 1864, wherein Meerut artillery and infantry barracks are described as intended for 30 men, 50 buildings facing east and west arranged in 4 parallel lines, with intervals of 40 yards from east to west, 30 from north to south, each barrack 50 feet long, 24 broad, 25 high, communicating through open arches with an inner verandah, outside another verandah, 1,800 cubic feet, 100 superficial per man. In the cavalry lines each building 210 feet long, 90 men, 1,900 cubic feet. The artillery occupied 2 large buildings each for 72 men; also 3 temporary barracks near the Rum go down, each containing a space 230 feet long, 51 broad, 23 high; roof supported by a row of arches, each 12 feet span; the barrack in 3 compartments, communicating by arches 12 feet span and 18 feet high; an outer verandah 9 feet broad on each side of the building.

Hospital of the Artillery—2 wings separated by dispensary; south wing, 2 wards each 60 long, 24 broad, 26 high; 20 patients; double verandah. North wing, 3 wards, one 96 long, for 32 patients; the other smaller one for 16, the other for 12—1,700 cubic and 72 superficial feet per patient; the latrine of the north wing standing on the east front of the large ward; the back faces the main building objectionably as regards effluvia.

The Infantry Hospital, for 100 patients, consisted of 3 wards, one 102 feet long, 24 broad, 26 high; the others 30 feet long—1,790 cubic feet per patient. There was also an old infantry hospital, besides one for the Royal Horse Artillery, the Female Hospital, adapted for 24 patients, the Cavalry Hospital, the east front of these buildings generally obstructed by walls, latrines, or other accessories.

Of the 35th Regiment, the first man attacked with cholera, July 11th, was a syphilitic patient in hospital, the disease in this instance contagious; the hospital matron, the wife of the hospital sergeant, also fatally stricken. Thirteen infantry barracks escaped. Slight cases were treated outside the dreaded hospital. The attachment of the men to Dr. Chambers, preventing panic, and the camping out on the only dry ground on the Mall proved beneficial.

The three artillery barracks, occupied by 4 Troop 1st Brigade Horse Artillery, 115 strong, escaped, whilst another troop had five cases. The recruit dépôt, 221 strong, suffered severely, for, according to Dr. Banister, these were growing lads with unsettled constitutions,

battling for the first time against the heat and depression of a tropical summer, and all had suffered in April, May, and June from bowel complaints and continued fever. The influence of panic, the necessity for early evacuation of barracks, the susceptibility of officers, the immunity of natives is alluded to.

In a certain house, in 1845, died General Considine; in the same low damp locality a young lady died in 1861; open drains, noxious privies, or marshy tanks blamed for the cholera. In a capital house in a park, on a clay soil, and surrounded by obstructed drains, an officer fell a victim. Five officers, overcrowded in one house, had, 35 servants, horses, stables, servants' families, cow-dung, and litter in close proximity, as if to welcome pestilence. The line of drainage divided the sandy surface of the native lines from the clay soil of the Europeans; and in every epidemic wherever this dry sandy soil was absent, or replaced by sterile clay, the disease proved most virulent. The prevalence of fever in certain localities north of Meerut in 1867 and 1868 brought out the elaborate report of the late Mr. Cutcliffe, who found miserable fever-stricken villagers living in filth on low wet spongy lands overgrown with rank vegetation, their drinking-water often polluted, the ground and well-water loaded with that efflorescence of carbonate, sulphate of soda, chloride of sodium, termed Reh, and owing to the Ganges and Jumna Canals most probably, he considered that subsoil, soakage, lodgment and stagnation of water, insufficient drainage, &c., might account for excessive disease. Cholera in 1872 was very severe. Such are some of the lessons of the past, and the teachings of experience have led to many improvements.

The indulgence of the reader is solicited for retrogressive prolixity in the endeavour fully to describe the popular station of Meerut.

PUBLIC HEALTH.

II.

IN our issue of July 29 we made some remarks on Mr. Simon's new report, confining them chiefly, however, to the subject of cholera and its prevention. In that same report—New Series, No. 1—the Medical Officer of the Privy Council and Local Government Board furnishes us with a concise statement of what may be expected from his office in the shape of reports. They will no doubt always illustrate the practical effect of such laws as may be in force for the prevention of disease; but this is not all, and it is interesting to observe the out-look of one so favourably placed as Mr. Simon. We will therefore

briefly summarise his statement of what he considers should be the nature of the annual reports to be in future made under the Public Health Acts.

He assumes that the Local Government Board will from time to time determine what degree of central vigilance as to the local prevention of disease shall be represented by its proceedings under the Act, and will regulate in accordance with such standard of work the staff by which the work has to be executed. The medical officer of the Board will annually give a report of the proceedings so taken. This will be substantially a report on the new sanitary administration of the country, from the standpoint of results; and which, so far as means for it exist, would aim at exhibiting, for the information of Parliament, what, year by year, are the chief existing excesses of disease in the several sanitary divisions of England, and what the relation of such excesses to insufficiencies of law or administration. Incidentally he thinks it would probably be of advantage to the public service that the reporter should use the same annual opportunity for submitting to the Board, with a view to publication, such new knowledge as the Medical Department might during the past year have acquired with reference to the prevention of disease, and such new memoranda of advice on sanitary subjects as the growing experience of the department might be held to justify.

From among the many points of local relation which the Board's sanitary superintendence must include, there is one which Mr. Simon specially mentions, with the acknowledgment that, in love and honour for his own profession, he regards it with warm personal interest; but believing that he may, nevertheless, without partiality describe it as of fundamental interest to the working of the scheme of recent legislation.

While watching, from the point of view of results, the action taken by local authorities throughout England for the better prevention of disease, the Board will be superintending the exact province of work for which the respective local authorities under the Act of 1872 are required to appoint their medical officers of health; and the inspections under the Public Health Act, 1858, will therefore, so far as they extend, give the Board knowledge of the working of that new institution in the various forms in which it is being tried throughout the country, and in which, in regard of about half the number of cases, the trial is with the Board's part-payment and particular responsibility. Such inspections, too, as bringing the Board's Medical Department into direct relation with the local officers of health, and giving the department opportunity to contribute any assistance in its power to the success of the local institution, will, where they extend, represent an object which the Royal Sanitary Commission, in making the recommendations on which the Public Health Acts of 1871 and 1872 were founded, put forward as an element of their scheme.

Mr. Simon says that to one in his position it must always be among the highest of ambitions to be able to see the experience of this department really conducive to the information and influence of younger fellow-labourers in other parts of the same great field of public service; and it would be affectation to deny that, during many early years of the new organisation, relations in that sense between the central and local services may often be of important, and sometimes of indispensable use to the latter. Nevertheless, he thinks that, though from the nature of the case the relation in these earlier years must

chiefly consist in assistance which the central office can so render, succeeding years will more and more bring the central office under obligation to local contributors of knowledge, and to local illustrations of progress. And year by year it will surely grow to be among the most useful, as it must also be among the happiest, duties of the annual reporter under the Public Health Act, 1858, to represent, for the information of all the officers of health of the kingdom, such additional fruits of scientific observation, and such new evidences of practical success, as will have come to the Board's knowledge from among their number.

Medical officers of health will be encouraged by these words, feeling that such services as it may be their lot to render to sanitary science will not be unappreciated.

---

## Notes on Current Topics.

---

### Sick Torture in a London Workhouse.

WE read with much difficulty of credence a report made last week to the Guardians of the Holborn Union of the existence of an atrocity which it is inconceivable could have occurred in the heart of London, and in a public institution. The master of St. Luke's Workhouse reported that on the 14th ult. he discovered a dying man, named Joseph Hardinge, aged 64, with his feet tied to the bed by means of two handkerchiefs, and a sheet so tightly tied over his chest to each side of the bed that he (the master) could not insert his hand between the bandages and the man's body. He had been thus pinioned for many hours, and died early on the following morning. He was in the last stage of pneumonia, and according to the evidence of one of the visiting committee, "was allowed to writhe in torture for several hours bound in these cruel swathes."

---

### The Plea of Moral Insanity.

OUR readers will recollect that in a celebrated murder trial some time ago an attempt was made to obtain an acquittal for the prisoner on the plea that he was the victim of an innate depravity of mind which should be considered to render him irresponsible for his acts. It was admitted that there was no symptom or history of previous alienation of mind, and the theory of moral insanity was based upon the supposition that the prisoner appeared to be unable to realise that his crime was crime at all, and considered himself self-justified in what he had done. In spite of the evidence of a very distinguished psychologist, who thought that this condition of mind was enough to constitute irresponsibility, the prisoner was very properly convicted and hanged. To deal otherwise with him would be to admit that the law was to be guided by his own estimate of his guilt, and we observe that this view has been confirmed last week by Mr. Justice Brett, who in charging the grand jury at Exeter, pointed out that for a person to be freed from the result of crime it was not sufficient to show that he acted differently from persons in the ordinary course of life, but it must be shown that he was so far insane as not to know the nature of the act he was committing, and not to know right from wrong. The

duty of those who had to administer the law was not to act upon their view of what the law should be, but to administer the law as they found it.

### Remarkable Decrease in Dispensary Relief in Ireland.

ON comparing the figures for the two last years the Local Government Board observe that there has been a decrease for the last compared with the previous year in each class of cases in all the provinces. Of the cases attended at the dispensaries there has been a decrease of 715 cases in Ulster, of 5,288 in Munster, of 1,291 in Leinster, and of 5,499 in Connaught; producing a total decrease of 12,793 cases. Of the cases attended at the patients' homes there has also been a uniform decrease for the last year, amounting to 2,757 cases for Ulster, 6,068 for Munster, 8,177 for Leinster, and 2,208 for Connaught; giving for all Ireland a decrease in dispensary cases of 12,793, and of domiciliary cases of 19,210; such uniform decrease in both classes of cases, between two consecutive years, has occurred only twice before since the establishment of the present dispensary system, viz., between 1865 and 1866, and between 1870 and 1871. During the same period of twenty years the annual number of cases receiving gratuitous dispensary relief has risen from 690,411 to 692,026, notwithstanding the decrease during the same time of the population of Ireland, not falling much short of a million. In last year's report the Local Government Board had occasion to remark on comparing the numbers of cases for the then two last years, a great diminution of dispensary cases in each province, amounting in the whole to 34,321 cases; but, on the contrary, an increase of cases attended at the patients' homes, giving a total of 17,075 cases.

### Female Doctors.

WHILE we have from the first urged upon the profession the inexpediency of offering any factious opposition to the admission of women to its ranks, we have demanded, in the name of that decency which is apparently considered effete, that females should acquire their knowledge with due regard to those conventionalities which we usually call modesty, and that those ladies who are seeking admission to medical practice should pursue their studies without offence to that prejudice in favour of decency to which some of them appear to be insensible. We have, moreover, expressed our belief that a few years' experience would prove that female medical doctoring is not a want of the day, and is beyond the physical capacity and discordant with the anticipations of the great majority of the sex.

The *Saturday Review* takes exactly a similar view of the matter in a recent able article.

"The medical profession," it says, "seems to be the special object of women's choice, because, as is said, women, being good and tender nurses, are supposed to be therefore easily convertible into skilful physicians and dexterous surgeons. It is said that women are specially well fitted to attend to the diseases of children. It is also asserted that there is a scarcity of medical men, and the women might supply this deficiency. It does not require much examination to see that these arguments are feeble and fallacious. It does not at all follow that a kind and watchful nurse will become a skilful and experienced physician, full of resources, ready in applying them, or a

dexterous surgeon, cool and unfalter in difficulties that would paralyse a weaker heart. It does not appear to be true the women generally desire to be attended by women, and it is absurd to suppose that less skill is required in the treating the diseases of children than of grown up persons. Lastly, we believe that the reputed scarcity of medical men is due, not to want of young men ready to enter the profession, but to the greater strictness of the examinations which it is necessary to pass—a difficulty which must equally present itself in the case of women, and which, as a recent case is shown, is not likely to be surmounted by them. No one who knows what the course of study of a medical student is can doubt that a woman must be of very exceptional character if she can pass through these scenes and still retain undimmed those characteristics which are the beauty and ornament of women's life. If, again, women do, as some few have done succeed in obtaining entrance to the medical profession, can she be supposed to be equal to all the emergencies, to the labour and the fatigue which the practice of that profession entails? All cannot settle in fashionable West End localities, where labour is light, and where duties are almost pleasure. The rough must be accepted as well as the smooth. Have women ever made themselves acquainted with the life of a medical practitioner in a thinly-peopled region of Wales or of Westmoreland—riding on horseback to places where no vehicle can travel, doing the work by night, for whom the day does not suffice, regardless of rest, careless of weather."

### Cough.

SOME new experiments on cough are related in *Virchow's Archives* by Dr. O. Kohte, of Strasburg. The first experiments of a scientific character on cough were made by Krimer, 1819. He considered cough as caused principally by irritation of the pneumogastric nerves. Afterwards Budge asserted that only primary cough was generated in the larynx. Then Truvelhier caused cough by irritation of the pneumo-gastric, which observation was confirmed by Romberg and Budge. After this Rosenthal concluded from experiments, that irritation of the superior laryngeal nerve is the frequent cause of cough. Recent experiments published by Nothnagel indicate that irritation of the membrane of the trachea and bronchi causes cough, and that not only the superior laryngeal nerve, but also other fibres of the pneumogastric, are apt, when irritated, to call forth cough.

Clinical observations lead Dr. Kohte to the belief that the physiological experiments on cough are not concluded. He, therefore, made a series of experiments with dogs and cats, without the application of narcotising substances. The cough was originated by mechanical, chemical, thermal (ice), or electrical irritation.

His results are given by the *Detroit Review* as follows:

1. *Larynx*.—By former experiments it is already proved that cough may be called forth by irritation of the larynx. The free margin of the vocal cords did not prove to be irritable. The inter-arytenoid fossa was very sensitive, and likewise irritation of the glosso-epiglottic plica and the ary-epiglottic plicæ caused cough.

2. *Parenchyma of the Lungs*.—The author could not decide the question, if irritation of the parenchyma and the alveolæ causes cough or not.

3. *Trachea and Bronchi*.—There was scarcely any doubt that cough arises from the irritation of the mucous membrane of these organs. Irritation on the place of bifurcation acts most powerfully.

4. *Pleura*.—Clinical observations speak for the appearance of cough in many cases of simple pleuritis. The same is proved by the author's experiments. Cough could be called forth with ease by irritation near the root of the lungs. Sometimes he applied ice, sometimes tincture of iodine or simple pressure, for this purpose. Irritation of the pleura costalis produced cough, but irritation of the pleura pulmonalis did not.

5. *Pericardium*.—Though pathological observations are in favour of the view that irritation of the pericardium produces cough, experiments failed to support it.

6. *Pharynx*.—In most cases irritation of its mucous membrane produced cough.

7. *Œsophagus and Stomach*.—Cough of a more croupous character was caused by pulling and pinching of the œsophagus, and by electrical irritation of the same. Simple irritation of its mucous membrane was ineffectual. Experiments on the stomach had only negative results. But there is no doubt that sometimes there will be noticed cough originated by irritation of the pneumogastric; for instance, when worms are present in the stomach or duodenum, or in cases of cancer of the stomach.

8. *Pneumogastric, Superior Laryngeal, Recurrent, Pharyngeal Nerves*.—Mechanical irritation of these nerves, except the recurrent, caused in all cases cough. Experiments with the recurrent had only negative results. When the author cut through the pneumogastric of one side, and then irritated the bronchi and pleura of the same side, he observed cough after a while. This proves a connection of fibres between both pneumogastric nerves.

9. *Central Cough*.—As some authorities consider the observations made in this respect as not decisive, the author thought it necessary to experiment on the central organs. He found that mechanical as well as electrical irritation of the cerebellum and medulla oblongata originated cough.

10. *Centre of Cough*.—Based upon his experiments, the author thinks that this centre lies a little higher than that for the muscles of inspiration.

### The Plague.

THE plague has again broken out on the Lower Euphrates and in Northern Africa, and has appeared principally in those localities which were the scenes of former outbreaks. It first appeared in February last, in a tribe of Affij Arabs, numbering about 3,000, of whom 250 fell victims in the two following months. The principal symptoms observed were: Intense fever, delirium, vomiting, diarrhœa, buboes in the groins and armpits, generally followed by death in a short time.

### Scarlatina in Ireland.

THE Irish Registrar-General calls attention in his last weekly report to the continued prevalence of scarlatina in Dublin. The zymotics caused in the week 31 deaths in Dublin, of which 13 were from the disease, and this number completes a tale of 546 deaths which have resulted from the epidemic within ten months. At the last meeting of the Mullingar Guardians a letter was read

from the Local Government Board enclosing observations appended to a report of the medical officer of the Tyrrellspass Dispensary District, in which he states that a very severe epidemic of scarlatina had been prevalent in the district, and had been increasing for the last fortnight, but the latter cases seem somewhat milder.

A similar report was also forwarded in which it was stated that scarlatina and measles had been very prevalent in the Mullingar District for a considerable period, and that several cases of the former disease were of a severe type, and terminated fatally.

### Surgeon-General Beatson.

A CONTEMPORARY has the following biography of the late Surgeon-General George Stewart Beatson, M.D., C.B., Honorary Physician to the Queen, and Principal Medical Officer, British Forces in India:—

"Dr. Beatson had been in delicate health for some time past, suffering from occasional and severe attacks of fever. The immediate cause of his death was, we believe, disease of the heart and pleurisy. We extract the following short account of his career from the *Civil and Military Gazette*:

"He was born on the 6th of May, 1814. He entered the Medical Service as an Assistant-Surgeon on the 13th July, 1838, was promoted to Surgeon on 28th August, 1846, to Deputy Inspector-General of Hospitals in December 1858, and to Inspector-General in May, 1863. As Surgeon he served in the 51st Light Infantry throughout the Burmese War of 1852-53, was present on board the steam frigate *Feroze* in action on the Rangoon River, in the capture of the great Dagon Pagoda, and at the defence of Prome—medal with clasp for Pegu. He came out to Madras as Deputy Inspector-General of the British Forces in that Presidency in June, 1860, and attaining the position of Inspector-General, was sent to the Bengal Command as Inspector-General of the British Medical Department in India on the 1st of May, 1863. On expiration of his tour of service as such, he went home in March, 1868, and for the second time came out to Bengal as Surgeon-General and Principal Medical Officer, British Forces in India, on the 13th of March, 1872."

"The *Gazette of India* publishes the following notification, dated the 9th of June:—

"His Excellency the Governor-General in Council has received with much regret the intelligence of the death, at Simla, on the 7th inst., of Surgeon-General G. S. Beatson, M.D., C.B.

"Dr. Beatson had twice, in the course of a long and honourable career, filled the highest post in the British Medical Service in India with credit to himself and advantage to the State, and the Government of India sincerely lament the loss of this valuable public servant."

### The Apothecary's Oath.

Now that the Pharmacy Bill is in a forward state, the following may be suggestive:—

Who is the guardian saint of the apothecaries we do not know; but somebody has disinterred an ancient oath which formerly had to be taken by every French pharmacist. It runs thus:

"I take to witness, before all, God the Creator of the Universe, in three persons, that during the whole of my life I will observe that which follows:

"I will live and die in the Christian faith. I will honour my parents. I will honour the physicians and masters under whom I have studied. I will never say anything that shall be injurious to the seniors of our order, or to others. I will adorn with my best the dignity of the art, and I will not reveal its secrets. I will do nothing im-

prudently nor through hope of gain. In acute sickness I will not give purgatives without the order of the physician. I will not touch the secret parts, except to apply remedies to them. I will keep the secrets of the patients. I will administer no poison, neither will I allow it to be administered, even to my enemies. I will not give an abortive remedy, even to provoke the expulsion of a foetus, except upon the order of a physician. I will not alter the prescriptions of physicians. I will never substitute one remedy for another without their knowledge. I will discourage the fatal practice of empirics. I will refuse to no person my legitimate assistance. I will not keep in my pharmacy stale or badly prepared medicaments.

"In making and observing these rules, may God assist me. *Ainsi soit-il!*"

### A Prolific Man.

THE American journals record the case of a German living in Pennsylvania who is the father of forty-one children. He was married in Germany in 1840. His first wife produced in eight years seventeen children, twins in two births, and triplets in four births. His second wife had fifteen children, of which ten were consecutive twins. His third and present wife has already presented him with nine children. Happy man! and should we say woman, to obtain such a husband!

### Hydrophobia occurring in Two Years and a Half after the reception of the Bite of a Rabid Dog.

DR. FERCOL has lately read before the *Académie de Médecine* a case of this affection which presents some points of interest.

The patient, a medical man, æt. 48, came to his *Maison de Santé* at eight o'clock one morning. His manner was strange and "*égaré*," his answers short, pupils dilated, and he had passed the previous night in so excited a state that he had written over fifty letters. He had an intense dislike to liquids, and he brought with him some oesophageal bougies to see and make him drink in spite of himself. He asked for an emetic to get rid of the bile which was choking him; he also asked for a bath, and on presenting to him a mirror, he immediately turned away his head, and had at the 'same time a severe laryngeal spasm, and looked like a man who had suddenly been plunged in cold water. On being presented with a tumbler, even when empty, he immediately pushed it away; a handkerchief shaken before him gave the same results. He had eaten nothing for two days; he felt his mouth dry. On examination he was found to have a scar on the left hand, between the second and third finger, where he admitted he had been bitten long previously by a rabid dog; he felt no pain, and never did during his illness, in the spot, but had some at the point of the biceps. The case proceeded from bad to worse, with severe laryngeal spasms, choking sensations, and spitting, and he finally became intensely delirious and ungovernable. He was under observation from eight in the morning of the 18th June, and died at three in the morning of the 20th, 1874.

On inquiry it was ascertained that he was bitten in December, 1871, by a pet dog, which he had observed for several days before the accident, to have been irritable and snapping at everything in the way, and which was finally

killed and examined by a veterinary surgeon, who pronounced it to have had hydrophobia.

Two other persons had been bitten, but after some days' interval, by the same dog, but did not suffer. The treatment consisted chiefly in hypodermic injections of morphia.

On post-mortem examination, the bronchi were found full of frothy mucus, a few tubercles in the lungs. The dura and pia mater of the cord were congested, the vessels distended, with induration of the cauda equina, and ecchymoses at the origins of the intercostal nerves.

### The Privy Council Rules for the Management of Lunatic Asylums in Ireland.

IN the House of Commons last week, Mr. Synan asked the Chief Secretary for Ireland if he could give any assurance that the Irish Government will revise the rules and regulations for the Government of lunatic asylums in Ireland under the 8 and 9 Vic., cap. 107-8-9, with a view "to alter or revoke" the rule in relation to tenders which has given offence to some governors of lunatic asylums in that country.

In reply, Sir M. H. Beach said that the rules and regulations for the government of Irish lunatic asylums have recently been carefully revised by a committee of the Irish Privy Council specially appointed for the purpose, and consisting of gentlemen whose names gave weight to the decision they had come to. One of the rules made after this revision was objected to by the Governors of the Limerick Lunatic Asylum, and on an inquiry being addressed by the Irish Government to the governors of other lunatic asylums in Ireland, with a view of ascertaining whether they also objected to the rule, it was found that few, if any, agreed with the Governors of the Limerick Lunatic Asylum. The rule to which they objected was one requiring that rejected tenders should be sent to the office of the Inspectors of Lunatic Asylums in Dublin for their inspection. The Governors of the Limerick Lunatic Asylum are willing that tenders should be inspected by the Inspectors of Lunatic Asylums on their visit. The difference seems to me so unimportant that I confess I am surprised at the strange objection made on the part of the governors of the lunatic asylums, but as some of them have resigned, and I understand that others are likely to, I shall consider if it is possible to alter the rule in accordance with their wishes. It is certainly important, however, that there should be a uniform rule for the whole of Ireland.

We are gratified that the very dignified course adopted by the Governors of the Limerick Asylum, who refused to hold office any longer, has induced the Chief Secretary to contemplate an alteration of the obnoxious rules. We may venture, however, to remind Sir M. H. Beach that the rejected tender rule is nothing more than a selected subject of objection on the part of boards of governors, and that its amendment will go a very little way towards removing the causes of dissatisfaction. The actual grievance of which not only that of Limerick, but most other boards complain, is that the whole policy of these new rules is that which has for so many years been pursued by Dr. Nugent, the concentration of all authority in the inspectors and their nominees, the president superintendent, and the lowering of the function of the board

of governors and the visiting physician. These rules aim, as far as it can be confessed by the author of them, at the hedging of the officers from any responsibility to the public; and we maintain that that policy is most dangerous to the Irish lunacy system.

### The Question of Bony Union in Intra-Capsular Fracture of the Femur.

M. HOUEL, Curator of the Dupuytren Museum, has lately exhibited several preparations from this museum which prove that bony union in this form of fracture is not so rare as is generally supposed.

### New and Coming Books in Medicine, Surgery, and Science.

BARRER (George), *The Student's Pocket Companion to the British and London Pharmacopœias of 1851 and 1869.* 7th ed. 5s.

Braithwaite, A. *Commentary on Midwifery and the Diseases of Women and Children.* 2s.

Foster (Balthazar), *Clinical Medicine: Lectures and Essays.* 10s. 6d.

Foster (M.), *Physiology.* 1s.

Garrod (Alfred Baring), *The Essentials of Materia Medica and Therapeutics.* 12s. 6d.

Pereira (Dr.), *Elements of Materia Medica and Therapeutics.* 25s.

Schaible (Charles H.), *First Help in Accidents.* New ed. 1s.

Thomson's *Conspectus.* Adapted to the British Pharmacopœia. New ed., with a Supplement containing Notices of the New Medicines and Preparations contained in the Additions of the British Pharmacopœia. 6s.

Watts (Robert George), *Asthma: A Practical Treatise.* 1s.

Blake (C. Carter), *Sulphur in Iceland.* 1s.

Grove (Sir W. R.), *The Correlation of Physical Forces.* 6th ed. 15s.

Macmillan (Rev. Hugh), *First Forms of Vegetation.* 2nd ed. 6s.

#### Announcements.

*Diseases of the Kidney and Urinary Derangements.* By W. Howship Dickinson, M.D. New ed. 8vo.

*A Dictionary of Medicine.* Edited by Richard Quain, M.D. 1 vol. 8vo.

*On the Maintenance of Health: for Lay Readers.* By John Milner Fothergill, M.D.

*On the Curative Effects of Baths and Waters: being a Handbook to the Spas of Europe.* By Dr. J. Braun. Trans. by Herman Weber, M.D.

*Medical Charity: its Abuses, and How to Remedy Them.* By John Chapman, M.D.

*The Star Depths: or, Other Suns than Ours.* By R. A. Proctor. Cr. 8vo.

*The Elements of Physics.* By Neil Arnott, M.D. 7th ed. Edited by A. Bain and A. T aylor.

*Introduction to Experimental Physics.* By Adolf F. Weinhold. 8vo.

*The Transit of Venus.* By George Forbes, B.A.,  
*A Popular Dictionary of Inventions, Origins, and Discoveries.* 8vo.

### Precocious Marriages.

THE Registrar of Providence calls attention to the defective marriage laws in the Island of Rhodes, which allow minors to marry without the knowledge or consent of their parents, and he gives, in example of the disparities, the following illustration in one year: 18 and 14; 17 and 15; 16 and 15; 61 and 15; 76 and 13. As he remarks, Providence is thus converted into a vast Gretna Green.

### Functions of the Brain.

DR. H. P. VON PETERSHAUSEN epitomises for the *Detroit Review* some experiments on the functions of the brain, by Prof. H. Nothnagel, of Freiburg, and related in *Virchow's Archives*. Prof. Nothnagel has performed another series of experiments on rabbits, to ascertain the seat of the faculties of the different parts of the brain. At this time he chose to exclude from action the lenticular nuclei of the corpora striata (i.e., the gray centre of the extra ventricular portion of the corpora striata). The most prominent symptoms after destruction of the nuclei were the following: Voluntary motion is wanting; slight irritation of the skin causes movements of the irritated parts, or a jumping motion; the hemispheres are active and all physical processes are probably undisturbed.

By the extirpation of both nuclei must, therefore, be interrupted the nervous connection, which leads the psycho-motor impulses from the places of their origin in the hemispheres to the periphery. This agrees well with the clinical experiences, as every physician knows, that extravasations in one of the lenticular nuclei causes persistent hemiplegia.

Although not so definite, the professor adds his observations on the nucleus caudatus. He thinks that this is related to all those combined forms of motion, which may be called forth by a psychical act, and which after this continue to be automatical motions.

### Treatment of Incontinence of Urine in Children.

In a paper read before the Obstetrical Society of Dublin by Dr. Kennedy, he strongly advocated the following measures for the cure of this distressing complaint:—

1. Training patients to retain their water in the day-time as long as possible.

2. The use of the cold douche.

3. A moderate use of fluids towards night, and a total abstinence from tea.

4. The internal use of belladonna in gradually increasing doses, till its specific effects are produced. In referring to the action of this drug, he mentioned one feature about it as regards children, namely, their small susceptibility to its action; and that they bear it very much better than adults.

### Neglect of Vaccination amongst the Irish Poor.

COMPARING the numbers tabulated by the Local Government Board for the last two years, it appears that the number vaccinated of children under nine years of age, and therefore subject to compulsory vaccination, was less in 1873 than in 1872 by 23,343 cases. The Commissioners remark that the authorities responsible for carrying out compulsory vaccination through the dispensary medical officers should regard this as a very lamentable fact, and should be powerfully stimulated by it to use every effort to induce or compel the poor of their districts by persuasion, and the steady enforcement of the penalty imposed by the 8th section of the "Compulsory Vaccination Act," on parents failing to perform so obvious and imperative a duty by their offspring, to have their children protected against small-pox. The inevitable consequence of the apathy from which this state of things arises will be the accumulation year by year of persons always liable to small-pox if exposed to infection, and certain to fall victims to it in great numbers in all recurrences of epidemics of the disease. In the other class of cases, those of persons not liable to compulsory vaccination, the great decrease of vaccinations for the last compared with the previous year has taken place of 120,268 cases—a circumstance, however, of much less consequence than the decrease between the same years among children under nine years old. The large amount of vaccinations of the former class in 1872 was quite exceptional, was entirely the effect of alarm, and consisted in great measure of re-vaccinations. The number of vaccinations of this class had steadily fallen between 1865 and 1870 from 71,982 to 5,163. Next year the number rose, by the effect of commencing alarm, to 40,836, and in 1872 to the unprecedented amount of 139,822 cases, and has now fallen to 19,554 for last year, and it may be anticipated that in the absence of alarm the number will continue to decline in the following years as it did between 1865 and 1870.

### Novel Dressing for Wounds, and for Stopping Bleeding.

M. VIGIER recommends a paste made by mixing two parts of modelling clay with one of glycerine, and so making a paste which will be found convenient as a dressing and preservative at the same time.

### [ Medical Relief Expenditure of the Past Year in Ireland.

ACCORDING to the table published by the Local Government Board there has been an increased expenditure under the head of medicines and medical appliances for 1873 compared with 1872 of £609—an increase not in accordance with the decrease above mentioned in the number of patients treated in 1873. The rent of dispensary buildings has been increased by the small sum of £69, and the salaries of the medical officers and apothecaries have been raised by about the usual average amount—viz., £1,531. Under the 3rd and 6th heads there has been a less expenditure for 1873 than for 1872—viz., £95 less for books, forms, stationery, &c., and

£5,063 less for vaccination expenses, occasioned by the great decline in the demand for vaccination and re-vaccination consequent on the subsidence of the late severe epidemic of small-pox, and the panic attendant upon it.

The average poundage on the Poor-law Valuation in Ireland, now amounting to £13,408,226, to provide for the above-mentioned total expenditure, was 2'49d., which is slightly under that for the year before—viz., 2'55d.

### Urea in Vomited Matter.

THE interesting assertion is made by Dr. Juventin, of Paris, in a recent thesis, that the excretion of urea by the mucous membrane of the stomach is normal, and goes on in an amount proportionate to that contained in the aqueous portion of the blood. The blood in the normal state contains 0.16 centigrammes of urea to the litre, according to Picard's analyses. The quantities of urea contained in the vomited matters he determined by the process of M. Bouchard.

### Diminution of Infant Vaccination in Ireland.

THE Local Government Board call attention in the last report to the diminution of vaccinations of children then under eight years of age in Ulster, Leinster, and Connaught. This year the diminution in question is common to all the provinces. In Ulster the vaccinations of children under nine years of age were fewer in 1873 than 1872 by 3,679 cases, in Munster less by 11,861 cases, in Leinster less by 6,031 cases, and in Connaught less by 1,772 cases, giving a total decrease of 23,343 cases. It is certainly very strange that, while the small-pox panic drove multitudes of adults to the dispensaries to procure protection for themselves, it appears to have had the effect of deterring parents from seeking the same protection for their young children—a contrast not easy of explanation, unless perhaps we may conjecture that mothers were averse to bring their children to the dispensaries, frequented by unusual crowds, from the not altogether groundless apprehension that they would there be exposed to infection of small-pox.

### New Medico-Pharmaceutical Journal.

IT has been formally announced in the last issue of the *Chemists and Druggists' Advocate* that that journal will, from this month, be incorporated with, and published as, the *Medico-Pharmaceutical Abstract and Review*. The object of the *Medico-Pharmaceutical Abstract and Review* is stated to be to bring therapeutics and pharmacy into more intimate and useful relation, and to constitute a recognised medium of intercommunication and practical co-operation between the allied professions.

### Superannuations in the Irish Poor-law Medical Service.

WE learn from the latest Local Government Board Report that eleven medical officers of dispensaries and one workhouse medical officer have been superannuated under the Poor-law Medical Officers' Superannuation Act in the course of the year, all of whom have been awarded two-thirds of their salaries, the highest sum permitted by law.

A VERY melancholy occurrence took place last week in the south of Ireland by which a member of our profession lost his life. Dr. Kenelly, of Limerick, while dancing at a friend's house, at Lisdoonvarna, fell, and received so serious an injury to his head, that he died the same night

THE quarterly returns of the dispensary medical officers of the numbers of cases of scarlatina, small-pox, and fever attended by them in the year ended September, 1873, as published by the Irish Local Government Board, indicate diminution in each of these diseases in this compared with the year before. The cases of scarlatina were fewer in 1873 than in 1872 by 2,579 cases, those of small-pox by 9,381, and those of fever by 1,150. Scarlatina is severely prevalent in Dublin just now.

It appears from the Report of the Irish Local Government Board that additional appointments of midwives have been made during the year in six districts—one in each of four, and two in each of two districts. These most useful appointments have now been sanctioned in 193 dispensary districts. The Board reiterates its great regret that they have not been more generally adopted, as they are persuaded that they are well calculated to prevent much suffering to women in labour, and even, not unfrequently, to save life.

### ON WINES OF PORTUGAL.

WE find it was by no false inspiration that we drew attention in our number of June 3rd to the extraordinary exhibition this year, at Albert Hall, of wines, the produce of Portugal, the most extensive display that has ever been made as yet of produce from a single land. If it has obtained little of the notoriety which might have been expected here, this has happened from causes of an artificial and extrinsic nature, which need not be particularised. The path of commerce is often devious and indirect till straightened by the criterion of a judgment impartial and well-informed. Thus it is that the exhibition of Portuguese wines in London has created less sensation than at the Paris Exposition, undertaken with far inferior means and on a far smaller scale of magnitude—an undertaking which was a considerable source of interest and even of surprise to the French, and which served immensely to stimulate a trade which even before had no mean proportions. At least this exhibition, one might think, would prove of interest to the medical world—the use of wine, and especially port wine, being not smaller in great emergencies than it formerly was, and it is even more relied on now than in the preceding generation.

But this interest has failed to work, if we may judge by our contemporaries of the Medical Press. In one of them, most expansive and knowing about wines—the omission is easily accounted for, so natural is it with those we have wronged to look at them with an unfriendly eye. But what does the *Lancet* say? How deals it with so large a fact? This journal, too, has its commissioner who visits the cellars of the International, and he is not a little scandalised, it seems, to find so many brokers in the Temple; and yet the most lively exception to this rule—the most notable and standard exception, he passes without breath of compliment, indeed, without comment or remark. To Krun, Tartary, to California he bestows a fair measure of space, and accords them the blessing of his praise; to Portugal no single word. Now, Russia is a very extensive country, and so is America too, but scarcely are they the vineyards of the world; but Portugal is that every bit—her vales and hills are one large vineyard; the variety of

her productions is so great—so great her adaptability to wine production, that it has been even proved to demonstration that by merely varying the processes of manufacture there is no wine now drank or known in the market which she could not furnish on demand. At present there lay waste in Portugal some million *hectares* of land, little capable of any other cultivation, but admirably suited to the cultivation of the vine. It is next to nothing, then, that the country has doubled her production; she is fated to form the stock supply to other countries in their commerce, or a sort of backbone to all other feeble growths. The Douro wines she has sent us this year are chiefly of the third, or lowest class *de ramo*, those consumed in the wine-shops of Oporto, some few new wines of a better quality being included. The general idea has been to send such as are least familiar to the British public, and such as will serve to establish an acquaintance with wine of the last year's growth. It is thus that the Portuguese exhibition will be found rather a school of instruction to the passer-by than a bower of idleness and delight. The Epicurean may chance to be mortified, but the analogist will be certainly informed.

The Portuguese are now in the second relay of their exhibition: they exhibit some excellent Madeira and Carcavellos; but these need scarce detain us. The latter wine is not unknown in London, and are on some tables replacing sherry to a certain extent, though somewhat sweeter to the taste. It has received a great shock through the destructive prevalence of the *oidium*, from which it is recovering rapidly. It owes much of its quality, perhaps, to its production on upper cretaceous strata, near the mouth of the Tagus, the neighbourhood of the ocean being tempered by the land breeze, much as happens with the *Medoc* at the *embouchure* of the *Garonne*. This wine gains much by age, like other wines of Portugal! We need scarcely say that it ranks next to Oporto and Madeira, and it is no longer the monopoly of a single mercantile firm. Produced upon the lower cretaceous strata, we may mention next a red wine, which is far less known than it deserves to be, and which seems destined to play a great part in the future of imported wines—this is the Collares, also from the neighbourhood of the ocean, and differing much from that of Estremadura wines in general, even from those of its immediate neighbourhood. This wine has less body, with an agreeable softness; it is aromatic, and slightly acidulous; it has a rather low alcoholic strength, never more than 19° Sykes, and it comes in at one shilling duty. Collares costs one-and-ninety pence a gallon on the spot, and the freight is moderate; it is therefore very inexpensive. This is a wine which is calculated to displace beer, and even claret, in many an English home; compared with the latter it is more nourishing and satisfying; it is far more of a wine than it; nor is it heady, like beer. Though the Portuguese are in the habit of speaking of it as their beer, it is no contemptible wine, especially the better sort. Altogether, we may say of the Collares that it is a convenience we have been slow to adopt, which might serve to lend a grace to English life and remove from it an element of coarseness. It may even sometimes take the place of port; it serves generally to instil gaiety and to promote the flow of conversation. Collares has long served the tables of the Peninsular and Oriental Company, and deserves to be far better known. It is adopted in all families who have any connection with Lisbon, or we might say with Portugal, and we have found it installed in certain London households.

Of the specimens in the exhibition, we find them rather too new—too loaded with sweetness, and too harsh for first acquaintance and appreciation; with only a little age it becomes a charming wine. Beyond this we cannot but remark a fulness and body in these red wines generally much above the ordinary range of organic ingredients. We recommend to taste the Larradio, so much valued by the late King Louis Philippe that he was never without a large supply. Among white wines we recom-

mend the wines of Cartaxo for especial notice; there is no part of the kingdom where more care and attention is given to the wine production. We cannot but mention those of Bairrada, in Beira Baixa, and in the same province those of Castello Branco, among which is the celebrated *Coraad Beira*, which threw such a spell over the Duke of Wellington when he passed through this country that he was never without it abundantly in his cellar. Cuba, in the Alemtejo, also sends a most excellent white wine. And how can we omit to mention the Ribeira da Maria Alfonso? This wine may be rather said to surpass than compete with the Chablis, Grave, and Santerne. For drinking with oysters and suchlike gear, or in sultry weather in the shade, there is no such wine as this. With a little age it develops a delicious perfume, and it is a perfect wonder that it should remain unknown to the English *gourmet* or connoisseur.

### THE IRISH PHARMACY QUESTION.

THE Select Committee to whom the "Apothecaries' Licences Bill" was referred have agreed to the following special report:—

Your Committee having examined witnesses on the general questions raised by the provisions in the Bill submitted to them, have agreed to the following report:—

That a great deficiency is admitted to exist in Ireland of shops for the sale of medicines and compounding of prescriptions, by which serious inconvenience is entailed on the public.

That this deficiency arises from the exclusive privileges enjoyed by the Apothecaries Company, and from the high, and consequently expensive standard of qualification which it has thought it necessary to maintain, in accordance with the view that an apothecary should prescribe as well as dispense medicines.

It was suggested to remedy this deficiency by extending to Ireland the operation of the Pharmaceutical Society of Great Britain as it has been extended to Scotland; but your Committee recommend, in preference, the formation of a separate Pharmaceutical Society for Ireland, especially on the following grounds:—

a. That in Ireland there has been for many years a licensing centre for pharmacy. There was no similar institution in Scotland at the date of the extension of the English Pharmaceutical Society to that country.

b. That a local centre will be more conducive to the scientific and professional development of pharmacy in Ireland, this effect having been found to result in the analogous cases of the medical and surgical schools.

c. That the evidence we have heard leads us to believe that there exist in Ireland ample materials for the creation and maintenance of a Pharmaceutical Society.

Your Committee, feeling how important it is that complete reciprocity should exist between the Pharmaceutical Societies of Great Britain and Ireland, recommend that the examinations and qualifications in each of the three kingdoms be identical; the fees to be paid for examination, licence, and registration, be equal; and that registered licentiates of each kingdom shall have equal rights and privileges in the three kingdoms respectively.

Your Committee further recommend the adoption of a common register for both Societies, and that both be subject to Government supervision.

Your Committee suggest the following as a scheme for creating a Pharmaceutical Society for Ireland, viz., That the Society be formed by naming, in the first place, a certain number of fit and proper persons to be foundation members; with

power to make bye-laws, lay down a scheme of examination, and appoint a Board of Examiners, subject to the approval of the Lord Lieutenant in Council.

That a first Board of Examiners be appointed, with representatives from certain scientific bodies, which have expressed their willingness to co-operate.

Your Committee are of opinion that the new Society should be independent of the control of any existing body.

That after a date to be hereinafter named, no person whose name is not on the register of the Pharmaceutical Society of Great Britain and Ireland (with the exception of the licentiates of the Apothecaries' Hall of Ireland) should be permitted to sell any of the articles scheduled or to be scheduled as poisons under the Sale of Poisons Act, Ireland, 1870; or to compound prescriptions containing any such articles.

That the restrictions and penalties on the sale or compounding of medicines or poisons contained in the Act 33 Geo. III. c. 34, be abolished.

That the interests of existing traders affected by the foregoing resolutions as to the sale of poisons, should be protected.

It has been suggested to your Committee that the introduction into Ireland of men qualified by a shorter and less expensive process to practise as pharmacists would unjustly affect the interests of the licentiate apothecaries, who at present possess the exclusive right of practising, and have obtained it by a longer and more expensive process.

It would appear, however, that the more expensive qualification also confers a more extended power of practice, with which it is not proposed to interfere; and your Committee is of opinion that no such case of hardship would arise as to call for legislative interference.

Your Committee, in conclusion, report that it is not expedient to proceed further with the Bill referred to them; but that, in their opinion, the Executive Government should at the earliest opportunity introduce into Parliament a measure framed in accordance with the resolutions in this report.

### Literature.

#### BIOGRAPHICAL RECOLLECTIONS OF THE MEDICAL PROFESSION. (a)

THE author of "Biographical Recollections of the Medical Profession" has accomplished an arduous task; the task has been performed, too, with much tact, considerable judgment in arrangement, rare ability, and without a single display—within the five hundred and thirty odd pages that constitute the work—of the "gall and worm-wood" of personality.

Forty years of almost daily and uninterrupted intercourse with the persons and the circumstances of which he has written ought to go far to entitle the author to be heard; and, be he of the good old school, or of the modern one, who shall be now so fortunate as to obtain a copy of "Biographical Recollections of the Medical Profession," and commence the perusal of the first chapter, he will find himself so charmed by the truly natural tints thrown into this great picture of remarkable men and "good old times" as to be quite unable to resist pursuing the subject to the end, closing the volume with reluctance. Thus much to the general reader. What shall we say to the surviving medical contemporaries of the Coopers, Wardrop, the Cobbett, Wakley, Key, Ryan, Laurence, Elliotson, J. Johnson, Golding Bird, the Guthries, Todd, Thomson, Abernethy, Liston, Yearsley, Keate, Faraday, Copland, Robert Knox (we thought Robert Knox died at the Cancer Hospital

(a) "Biographical Recollections of the Medical Profession." By John F. Clarke, M.B.C.S., &c. London: J. and A. Churchill, 1874.

Brompton, where he held a small appointment), Walter C. Dendy, Sir H. Holland, Isaac Baker Brown, G. Hamilton Roe, Sigmond, Pennington, Curtis the Specialist, Marshall Hall, Brodie, Antony White—and what a goodly host besides? for all are treated of in this wonderful book? Tradition tells us that once upon a time a certain great man yearned to rest eyes on a world-renowned city, and stated that if the consummation of his wishes were afforded he would be thoroughly satisfied to quit the earth for ever. Bearing in remembrance such a simple illustration of the truly enthusiastic mind, and in words decidedly more philanthropic, we would not say to our old friends "Read these 'Biographical Recollections' and die," but we would say, and in verity, too, "Read them, and you will be very likely to experience some of the pleasing sensations of bright and buoyant youth again."

The style in which "Biographical Recollections of the Medical Profession" has been written is decidedly discursive, vigorous, and comprehensive withal. Opinions on persons and things are stated by the author boldly, impartially, and in a way not to be mistaken—evidently by a gentleman as capable of practically applying the "means to the end" as in theorising on both.

The various hospitals, their governments, powers, peculiarities, and staffs are summarised, and very fine pictures are drawn by the author of many remarkable incidents bearing on them that came under his observation.

No recent work with which we are acquainted, no essay which we have read, no discourse or lecture to which we have listened, seems to us so prolific of sound and good mental lessons for the young practitioner as may be found in this work—what to do and what to avoid, "pitfalls," and how to escape them, failures and successes, are set down, and the moral pointed where necessary, even sometimes to the detriment of the tale's adornment. In proof of what we state under this head, we refer the reader to the unhappy case of Dr. Elliotson and the University College Hospital, that of Curtis, Hale Thomson's case, the Cooper tragedy *versus* the *Lancet*, &c. Regarding Dr. Elliotson, the author thus sums up the case: "What a marvellous career was that of Elliotson. His father was a druggist in the Borough, where he amassed a considerable fortune. He had two sons, John and Thomas, who were sent to the University of Cambridge, where they graduated. John Elliotson was elected Physician to St. Thomas's Hospital at a comparatively early age, and did not seem at first destined to make a prominent figure in the profession. In the years 1827 and 1828 he commenced publishing in the *Lancet* short reports of cases under his treatment in this hospital; to each of these was appended a few clinical remarks, always to the purpose, always terse and epigrammatic. The result was, the unknown physician became in twelve months the talk of the town, and the recipient of £5000 in one year, his income the previous year being only £500. He was chosen to fill the Chair of Medicine at the University of London (as it was then called) and was made Senior Physician to the North London Hospital. He acquitted himself in these appointments admirably, and was one of the most popular teachers that ever existed. In the zenith of his fame, in the prime of life, in full usefulness, he unfortunately took up with mesmerism. Honest himself, he believed all others were equally honest, and hence the result. Elliotson and mesmerism stood and fell together. It is somewhat curious that the journal which in 1828 had laid the foundation of his fame and fortune should just ten years afterwards do so much to effect his ruin; but it was so."

The medical journalism of the time and the establishment of the *Lancet* are set down and given in detail. The "guns," great and small, get a passing word, from the boy George in Mill's office to William Laurence, William Cobbett, and Thomas Wakley, in the little room above it; but can no one inform us who was "Erinensis?" the medical Junius of the period. We are tempted to quote the author's comparison between one with whom for so many years he had been in daily association, the late Dr. Thomas Wakley, proprietor and first

editor of the *Lancet*, and two other celebrities: "Cobbett," says Mr. Clarke, "was unrivalled as a writer of pure English, able and interesting as a lecturer, but was a poor speaker. He was nowhere in debate; his miserable failure in the House of Commons is a matter of history. He who in his 'Register' was the terror of governments and the leader of a large portion of the thinking public was a 'by-word and a jest' before the assembled Commons. He was quite deficient in imagination, and halted, and even broke down in the discussion of subjects with which he was undoubtedly well acquainted. Not so Thomas Wakley. He was equally happy when addressing a low audience as in his place in the House, indeed, I know no one of his contemporaries who was his equal in this respect with the exception of O'Connell; but Wakley was considerably below the 'Liberator' in all respects: O'Connell was a great scholar, had a voice unsurpassed in richness and power, and broke out occasionally into eloquence which has never been surpassed in ancient or modern times."

The societies, the "Medical," "Medico-Botanico," "Medical and Chirurgical," &c., receive their meed of attention, and the position the author occupied at some of their meetings (and at other places) as the official representative of the *Lancet* is related with much humour. Here let us state that, since Mr. J. F. Clarke's work was placed in our hands, we happened to ask a question regarding a "family" portrait suspended in the dining-room of a patient of ours who resides a few miles from town; the answer given by the lady to whom the query was addressed startled us—"Oh, that (she said) is the portrait of 'Uncle Charles,' the doctor." "Charles who?" "Oh! Severn, of course; he practised in London, and had to do with *Bolt Court*." "Bolt Court—the Medical Society—was he a Fellow, eh?" "He held some office in that, I think—look;" and the lady left us, but presently returned heavily laden with a gigantic portfolio—verily a curiosity-shop of Dr. Charles Severn's doings and sayings and cuttings during the time he held the position of Secretary, at Bolt Court, to the Medical Society of London. On turning over a few pages our eyes suddenly dropped on a cutting from the *Medical Times*, October, 1839. The heading is "Meeting of Societies," and the article (for it is a leader) is written on "The London Medical Society at Bolt Court;" the names specially mentioned by the writer of the article are W. C. Dendy, Charles Severn, J. Lord, W. Headland, and J. F. Clarke, the author of the work of which we now write. The circumstance is alluded to in order that the existence of the portrait and portfolio may become known in the proper quarter.

Descriptions, racy and graphic, of the colleges and of medical schools of the period, and the principal celebrities attached to them, are given by Mr. Clarke—the Gerrard Street School, where Dermott (Principal) lectured on anatomy, physiology and surgery; Michl. Ryan on medicine, midwifery, and medical jurisprudence; and John Epps on materia medica, usually numbered 300 pupils. At this school Mr. J. F. Clarke studied. The fee for perpetual attendance was £22, we are informed. There were also the Great Windmill Street (Hunter's, where these very lines were printed) and the Little Windmill Street Schools in this district, and others dotted over the metropolis, and it would appear the "Irish element" led the way as medical school teachers.

An attempt to place before our readers quotations from this work with a view to show its intrinsic merits would be quite out of our power, even did space permit. Its merits are so manifold, and its aims so broad, enlightened, liberal, and important in a medical sense to student, practitioner, and indeed to the profession at large, that by reading the work only will the reader be able to form an estimate of its full value and the great advantage taken by the author of the opportunities afforded him to note the manners and the men he depicts.

In conclusion, we predict for "Autobiographical Recollections" a large and rapid sale, as we have said, it contains

many wholesome truths important to note just now. The work is printed in clear and bold type, on good paper, handsomely bound, issued in the publisher's most effective manner, and is destined to become a welcome guest in very many medical households.

### PRACTICAL PHARMACY. (a)

THE fourth edition of Parrish's well-known work will be welcomed both by the medical and pharmaceutical professions. The talented author has passed away, but his work has been judiciously entrusted to the care of Mr. Thomas S. Wiegand. In the space at our disposal it would be impossible to give anything like a complete analysis of this volume; we may safely say that it contains all the information which might be required by the compounder and dispenser of medicine. The first part of the book treats of the furniture and apparatus requisite in a compounding establishment; pharmaceutical processes are treated of in the second part; inorganic pharmaceutical chemistry follows; then, pharmacy in its relations to organic chemistry is considered; and, lastly, galenical and extemporaneous pharmacy are dealt with.

The work is eminently practical, and has the rare merit of being most readable and interesting, while it preserves a strictly scientific character.

For so extensive a book the inaccuracies are wonderfully few, and as far as we can judge, after a careful study of it, hardly worth mentioning. Aconella is not mentioned as one of the alkaloids of aconite, nor is there any allusion to the process of Fumouze for preparing cantharidin.

There is one feature to which we desire to direct special attention—namely, the Synoptical Tables, which must prove of the utmost value to candidates preparing for examination. The whole work reflects the greatest credit on author, editor, and publishers; it will convey some idea of the liberality which has been bestowed on its production when we mention that there are no less than 280 carefully executed illustrations. In conclusion, we heartily recommend the work, not only to pharmacists, but also to the multitude of medical practitioners who are obliged to compound their own medicines. It will ever hold an honoured place on our own bookshelves.

## Correspondence.

### THE MEDICAL PROFESSION.—SUPPLY AND DEMAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A medical friend of mine, lately home from the East, argued the point with me regarding the nature of an annual payment by families or firms to the medical adviser as being satisfactory. My friend stated that in every family in the East, where he was located, £15 per head was paid him, sick or not sick, per annum, and that he secured £2000 per annum by this arrangement. He asked why it was not so arranged in England. I informed him that in England respectable general practitioners found they would be literally worse than flunkies if they agreed to it. "Why?" said my friend. "I tell you why," said I: "The supply is greater than the demand—hence competition." And I informed my friend that several medical men, driving their carriages (God knows how they do it!), competed for a medical club of the trading class, 400 in number. One obtained the appointment, agreeing to attend whenever required, and supply medicine to the club in a radius of three miles of a certain house of worship for four shillings per head per annum! My friend returned to the East at once.

Yours truly,

A DISGUSTED MEMBER OF THE PROFESSION.

N.B.—I pay my dog-doctor 2s. 6d. a visit to my dogs when sick. Evidently the profession is not going to the dogs!

### ESTIMATION OF TOTAL NITROGEN IN URINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have but now seen Dr. Austin's last letter, and quite agree with your editorial append to it. Your correspondent has succeeded in surrounding simple questions with such a haze of misconception that a reply in detail would necessarily be a lengthy one, and I hesitate to occupy your space with any uninteresting matter, more especially since my last letter contains everything really necessary to be said on the subject.

The problem I ventured to draw the attention of the Surgical Society to is in some respects a novel one, the fluctuation in proportion of "residual nitrogen" in health and disease not having been as yet determined with care. This nitrogen usually bears a very small proportion to the nitrogen excreted as urea, hence care was necessary in arranging a plan of estimation which would be accurate and not too difficult of execution. The method I proposed is the result of much experiment, and in its development I have endeavoured to overcome by simple expedients that would be understood by any chemist the difficulties in the way of complete success. Dr. Austin, however, overlooking the fact that I have carefully guarded against objections that might be raised, and failing to appreciate the degree of accuracy required in an investigation of this kind, on the one hand rejects without trial my plan for estimating total nitrogen, and on the other waxes indignant that I should not have recommended for the estimation of pure urea in urine a process which Watt's in his great "Dictionary of Chemistry" states confounds together urea, ammonia, and uric acid, and whose use is also known to be attended with a variable loss of nitrogen, reaching sometimes as high as 8 per cent. Dr. Davy is, I am sure, too good a chemist to regard his process as an accurate one for the estimation of urea alone in urine. Dr. Austin, however, evidently considers an error of ten or fifteen grains in the day's excretion of nitrogen a mere nothing, whereas the quantity I wished to determine rarely reaches fifteen grains per day when the person experimented upon is in health. Need I say more to prove the uselessness of the discussions which now close, so far as I am concerned?

I am, Sir, your obedient servant,

J. EMERSON REYNOLDS.

52 Upper Leeson Street, Dublin, August 6th, 1874.

## Parliamentary Intelligence.

### HOUSE OF COMMONS.

THE OUTBREAK OF TYPHOID FEVER AT KILMAINHAM HOSPITAL.

SIR JOHN GRAY.—Before proceeding to put the question relative to the outbreak of fever at Kilmainham Hospital, of which I have given notice, I desire to make a few observations, but in doing so I shall certainly not detain the House for more than a minute. An outbreak of fever occurred at Newbridge Barracks, about twenty miles distant. The sewage water from that place was allowed to run into the Liffey, which forms the water supply for Kilmainham, being pumped

n for the purpose, and the rumour is that the medical officers have stated it was their opinion that the outbreak of fever arose from the drinking of impure river water, which had come direct from Newbridge Barracks, twenty miles distant. Great excitement necessarily exists on the subject, and therefore I beg to put to the right hon. gentleman the Chief Secretary for Ireland the question of which I have given notice, whether the Local Government Board have received any report from the medical or other officers of the Kilmainham Hospital, Dublin, respecting the recent outbreak of typhoid fever in that institution, and if not, will he, as President of the Board, cause an inquiry to be instituted and a report to be made as to the number of cases of typhoid fever that occurred in the hospital this year; the class of residence in which they occurred; the opinion of the medical officer, Dr. Carte, and of the medical gentlemen who were consulted, as to the immediate cause of the outbreak, and place such report upon the table of this House for the information of the sanitary authorities of the kingdom; and if, having regard to sanitary purposes, hygiene forms a necessary part of the education of medical officers licensed for the Civil Service, the Local Government Board intends to adopt any means of insuring that all medical officers hereafter to be appointed medical officers of dispensaries, and as such sanitary officers of their dispensary districts, shall produce satisfactory evidence of their knowledge of hygiene as a requisite qualification for such appointment.

Sir M. H. BEACH.—In reply to the first question of the hon. gentleman, I may state that Kilmainham Hospital is under the War Department in Ireland, and is not under the Local Government Board in Ireland, which has no official relations with it of any kind, and would therefore have no official knowledge of an outbreak of fever in the hospital. I understand, however, that, as the hon. member has stated, the water supply of the establishment is by no means good, and that there has been an outbreak of fever in the hospital. Since that time arrangements have been made for a better water supply, and works for that purpose are proceeding. With respect to the second question of the hon. member, which relates to an entirely different subject, there is no special hygienic qualification required at present from medical officers in Ireland; but the hon. member is no doubt aware that the legislation of the present session has imposed sanitary duties of an important nature on those officers. At present medical officers appointed to dispensaries must be physicians or surgeons, and I have no doubt that gentlemen holding that position will in future devote more attention to sanitary science, looking at the important duties now imposed on them, than, perhaps, has hitherto been the case.

## Medical News.

### University of London Pass List of First M.B. Examination.

—ENTIRE EXAMINATION—*First division*: Burton, Samuel Herbert; Carrington, Robert Edmund; Keetley Charles Robert Bell; Tirard, Nestor Isidore Charles. *Second division*: Blake, Henry; Fox, Thomas Colcott; Freund, Percy Herbert Edmund; Giles, George Michael James; Godfrey, Charles Walter; Gosling, Charles Edward; Hunt, Joseph William; Joule, John Samuel; Kidd, Walter Aubrey; Pinnell, Thomas Mark; Rossiter, George Frederick; Sankey, Herbert Richard Octavius; Snell, Edward Arthur; Symonds, Charter James; Trafford, John Foster. *EXCLUDING PHYSIOLOGY—First division*: Champneys, Henry Laurence. *Second division*: Baker, Albert De Wiuter; Bigger, Samuel Fergusson; Cross, Francis Richardson; Cuming, Charles Henry; Finch, Alfred; Pickup, William James; Ryley, James. *PHYSIOLOGY ONLY—First division*: Whitelegge, Benjamin Arthur. *Second division*: Batterbury, Richard Legg; Cooke, Edward Marriot; Duke, Herbert; Evans, Charles Walter; Ferrier, John Christian; Harrison, Charles Edward; Landon, Arthur Jermyn; Langley, John Geoffrey; Taunton, William Whitechurch, B.Sc.

**Malvern College.**—On Friday the annual speeches of this school were delivered before a large assemblage, and the Easter and Midsummer prizes were distributed by Mr. G. E. Martin. Among the honours announced by Mr. Faber as having fallen to the school in the preceding year were two open scholarships at Cambridge, one open exhibition at

Oxford, three places (2nd, 16th, and 19th) at the Cooper's Hill College, one Woolwich cadetship, one honourable mention for the gold medal of the Royal Geographical Society, and the first place in the final list of candidates for the East Indian Civil Service. Selections from the following plays were excellently rendered:—Shakspeare's "Merchant of Venice," Plautus's "Mostellaria," Seneca's "Octavia," Molière's "Les Fourberies de Scapin," Aristophanes' "Frogs." The Beauchamp, Gully, and classical prizes were then distributed by Mr. Martin, and the school dispersed till Monday, September 21st.

**The New Sydenham Society.**—The sixteenth annual meeting of the New Sydenham Society will be held in the Assembly Room, Norwich, to-morrow (Thursday, August 13th).

**List of Naval Medical Candidates** who were successful at both the London and Netley examinations, having passed through a course of instruction at the Army Medical School at Netley, and who will receive commissions as surgeons in the Royal Navy, August 1874:

	No. of Marks.		No. of Marks.
Saunders, E. H. ...	4,297	Collins, H. B. ...	3,179
Richardson, H. A. W. ...	3,825	Bennett, W. E. ...	3,150
Collet, J. A. ...	3,460	McKinlay, A. ...	3,032
Luther, E. W. ...	3,437	Hawton, J. W. H. ...	2,910
Bentham, R. ...	3,425	Mulock, E. R. ...	2,800
Ross, N. C. ...	3,394		

### Royal College of Physicians of London—Aug 5.—Admitted Fellows:—

Edward Liveing, M.D. Camb., 52 Queen Anne Street, W.  
Charles Paget Blake, M.D. Edin., Torquay.  
Henry Frederick Augustus Goodridge, M.D. Lond., Bath.  
Henry Gervis, M.D. Lond., 13 St. Thomas Street, S.E.  
Henry Heanes Cruicknell, M.B. Oxon., 58 Welbeck Street, W.  
William Withers Moore, M.D. Edin., Brighton.  
John Charles Thorngood, M.D. Lond., 61 Welbeck Street, W.  
Eustace Smith, M.B. Lond., 5 George Street, Hanover Square, W.  
Robert James Lee, M.B. Camb., 4 Savile Row, W.  
John Buckley Bradbury, M.D. Camb., Cambridge.

**The Peculiar People Again.**—Thomas Hinds, a member of this sect, was lately charged at the Woolwich Police Court with the manslaughter of his child, Joseph Hinds, aged two years, through neglecting to provide it with proper remedies and attendance during its illness. The coroner's jury had returned a verdict of manslaughter against him. The child was ill for three weeks, and frequently in convulsions; but the parents, following the practice of the Peculiar People, sent for one of the elders, named Hurry, who anointed it with oil, and prayed over it. A post-mortem examination showed that death resulted from pleurisy and pericarditis. The prisoner, who said that all he had done was for the glory of God, was committed for trial, bail in £100 being taken for his appearance at the next session of the Central Criminal Court. An opinion was expressed by the Bench that Hurry ought to be called up for judgment.

**The Forty-second Annual Meeting** of the British Medical Association commenced at Norwich on Tuesday, and will continue each day till Friday (August 14th). *President*, Sir William Fergusson, Bart., F.R.S. *President-elect*, Edward Copeman, M.D. An Address in Medicine will be given by J. Russell Reynolds, M.D., F.R.S. An Address in Surgery will be given by W. Cadge, Esq. An Address in Obstetric Medicine will be given by James Matthews Duncan, M.D., F.R.S. Edin., Lecturer on Midwifery and Diseases of Women and Children in the School of Medicine, Edinburgh. The business will be transacted in four sections viz:—Section A, Medicine; Section B, Surgery; Section C, Obstetric Medicine; Section D, Public Medicine. The honorary local secretaries are—Dr. J. B. Pitt, Norwich; H. S. Robinson, Esq., Norwich; Dr. Beverley, Norwich.

## Gleanings.

### Tincture of Iodine.

By P. CARLES.

It is well known that after being kept a certain time tincture of iodine is modified in its properties, and becomes unsuitable for certain uses, such as for injection in cases of hydrocele, tumours, &c. Guibourt was the first to call atten-

tion to the decomposition which this tincture undergoes, and in 1846 he brought it under the notice of the French Academy of Medicine. He rendered this decomposition palpable by mixing with two equal quantities of water an equal weight of each of two tinctures, of which one was recently prepared and the other was some months old. From the first all the iodine was precipitated, the supernatant liquid being scarcely coloured yellow; whilst the second, in consequence of the greater quantity of iodine which remained in solution, preserved a more intense colour. Guibourt attributed this facility of solution to the intervention of hydriodic acid which had been formed at the expense of the alcohol.

In 1850, M. Gopel presented a memoir upon the same question, and attempted especially to determine in what proportion the iodine diminished in the mixture, or in what proportion hydriodic acid was formed. For this purpose tincture of iodine was treated with reduced copper, which removed the free iodine, without touching that which was in combination, in such a manner that it became easy to estimate the latter under the usual form of iodide of silver. This mode of separation, however, could not be considered as very exact, for the cuprous iodide was slightly soluble and was ultimately estimated as hydriodic acid, thus affecting the exactitude of M. Gopel's results. His conclusions, nevertheless, were, that in the course of time hydriodic acid and hydriodic ether are formed in tincture of iodine.

Finally, in 1859, M. Commaille re-examined the same question and arrived at the conclusion that the alteration in tincture of iodine, far from being rapid, is very limited, and may almost be prevented by the employment of black bottles. M. Commaille the free iodine from that which was in combination by the aid of portions of starch paste, which he successively mixed with tincture until there was no further blue colouration; the hydriodic acid in the residuary liquor was then estimated as iodide of silver. This method of separating the iodine also appears to be inexact, for the large proportion of starch would take up also a portion of the hydriodic acid. Moreover, the figures given by these two authors present such a wide divergence that M. Carles has thought it desirable to publish the results of fresh experiments conducted in a different manner.

The following was the method of operating adopted:—The tincture of iodine was diluted with eight times its volume of water, and the mixture filtered in order to remove the greater part of the precipitated iodine. The clear filtrate was agitated with an excess of carbonate of baryta and again filtered. The baryta which had entered into solution in the state of iodide of barium was then estimated as sulphate, which allowed of a calculation being made of the quantity of hydriodic acid, formed at the expense of a given weight of the alcoholic tincture of iodine. In this way the author found that a tincture, after being prepared ten months (from August to May), and exposed in a white flask to diffused light, contained 1·12 part of hydriodic acid (HI) to 100 parts of tincture. M. Gopel had asserted that a portion of this acid exists in the tincture under the form of ether, but M. Carles, like his predecessor, has not been able to isolate it.

The question therefore arose, whether a normal tincture, to which the proportion of acid found had been added, would be susceptible of producing the bad results which are attributed to old and decomposed tincture. Practically, this has not been found to be the case, and M. Carles thinks the defect should rather be attributed to other products of which the nature is not at present known, but which he proposes to further investigate.—*Bull. de la Société de Pharmacie de Bordeaux*, xiv. 169.—*Pharm. Journ.*

### The Semeiologic Value of Permanent Deformities of the Hand.

THE following is a translation by the *Clinic* of a review of this work, edited by M. H. Heillet, and published by G. Masson, at Paris:—

Certain diseases are recognised by the particular, often characteristic, form which they impart to the hand. To unite these characteristics in a special work, to establish in pathology what may be called the *medical hand*, as legal medicine contains a complete and detailed account of the *professional hand*, such was the new and original subject upon which Prof. Charcot discoursed to his audience at the end of his course on pathological anatomy last year.

M. Heillet conceived the happy idea of collecting the words of this master, and possessed the talent of carrying the

work to a good end in the thesis just published, which has elicited the approbation of his reviewers expressed in a very satisfactory note. The author considers the deformities of the hand only in a diagnostic point of view. Thus he eliminates at once the malformations and deformities, consecutive to trauma and surgical affections, a fact which does not prevent some excursions over the domain of external pathology when necessary to clearness and precision.

Thus limited, the subject is still vast, but the 125 pages published prove that the design was fulfilled. In the first chapter, the author treats of progressive muscular atrophy, where we find, besides other deformities of the hand, the *atrophic grasp*, the *hand of the ape*. These deformities are produced by the muscular lesions consecutive to sections of the different nerves of the arm—cubital, median and radial. The deformities ensue upon atrophy of the muscles innervated by the different branches of the injured nerve. The radial deformity recalls that due to saturnine paralysis, *wrist drop*. This section is concluded with a description of the retraction of the *palmar aponeurosis*, and the deformity of tetanus.

In the second chapter are grouped the diseases of the nervous centres, and we find described successively the *leprous hand*, the *sclerodermic hand*, the *hysterical permanently contracted hand*, the *closed hand of old hemiplegics*, the hand called the *indicateur emphatique*, the *hypertrophic hand of cervical pachymeningitis*, and finally, the different deformities incident to *paralysis agitans*.

In the third and last chapter, the author discusses the interesting deformities due to general diseases, *gout*, *chronic progressive muscular rheumatism*, *Herberden's nodosities*, the *osteo-malacic hand*, the *Hippocratic hand*.

In all these cases the deformities of the hand are of great utility in aiding diagnosis; often they suffice alone to establish the nature of the disease; often they are the sole signs of the inception of disease, or, in the words of the author, they are epitomes of its progress.

The work is ornamented with plates, from the hands of a distinguished pupil of the hospitals, M. Richer. They exhibit to a remarkable nicety the deformities described by the author, who has given us, as the result of his labours, a new chapter in semeiology.

### NOTICES TO CORRESPONDENTS.

✂ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spread by attention to this rule.

DR. WARING CURRAN, Mansfield.—We have received your communication, with enclosure, which will appear in our next number.

ERRATA.—Dr. Campbell Black's lecture "On Bright's Disease" having been accidentally printed in our last impression without the corrected proof, the reader will kindly note the following errata: On page 104, "revealed an exsanguine," add "condition." For "marked destructive features" read "distinctive." A few errors of punctuation also occur.

### BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Statistics of Families. By C. Ansell.  
Atmospheric Electricity and Ozone. By M. Beard, M.D.  
A New Method of Treating Malignant Tumours by Electrolysing the Base. By Geo. M. Beard, A.M., M.D.

### VACANCIES.

Parish of Kensington. Non-Resident Dispenser for the Infirmary. Salary, £100 per annum, with dinner on the six days of attendance. Address the Clerk to the Guardians, Marlborough Road, Kensington, W.  
Ealing. Medical Officer of Health. Salary, £75 per annum, under the Health Act. Applications to the Clerk to the Board.  
Liverpool Northern Hospital. House Surgeon. Salary, £100, with board and lodging. Applicants must address the Chairman of Committee.

Macclesfield General Infirmary. Resident Medical Officer. Salary, £120, with board. Address the Secretary at the Infirmary.  
Newport Infirmary, Monmouthshire. Resident Medical Officer. Salary, £100, with board and lodging. Application to the Secretary.  
Sheffield General Infirmary. Assistant House Surgeon. Salary, £85 per annum, with board, &c. Applicants must address the Secretary.  
Hants County Asylum. Junior Assistant Medical Officer. Commencing salary, £80, with board and lodging. Candidates must address Dr. Manley, at the Asylum, Knowle, Fareham.  
Inverness District Asylum. Assistant Medical Officer. Salary, £70, with board and lodgings. Address the Chairman, at the Asylum.  
Norwich Pauper Lunatic Asylum. A Resident Medical Superintendent. A married man preferred. Salary, £150 per annum. Wife to act as Matron, at £30 per annum additional, with board and residence. Address, "The Committee of Visitors."

APPOINTMENTS.

- CLARKE, T. K., M.D., F.R.C.S.E., a Surgeon to the Huddersfield and Upper Agbrigg Infirmary.
- CLARKE, W. J., M.R.C.S.E., Consulting Surgeon to the Huddersfield and Upper Agbrigg Infirmary.
- CLENDENEN, W. E., L.R.C.S.Ed., L.A.H.D., L.S.A.L., Medical Officer of Health to the Urban Sanitary District of the Borough of Stafford.
- CRAIGTON, C., M.B., M.A., Medical Registrar to Charing Cross Hospital.
- CROW, J. W., L.R.Q.C.P.I., L.R.C.S.I., House Surgeon to the Hartlepool Hospital and Dispensary.
- GRANGE, W. D'OLY, M.B., C.M., Resident Medical Officer to the Royal Edinburgh Hospital for Sick Children.
- HARDYMAN, C. E., M.R.C.S.E., Medical Officer to St. George's Hospital.
- HUMBLE, T., M.D., M.R.C.P.L., Professor of Medicine at the University of Durham.
- HUNT, R., M.R.C.S.E., Assistant Resident Medical Officer to the Leeds Public Dispensary.
- JENKINSON, H., L.R.C.P.Ed., M.R.C.S.E., Senior Resident Medical Officer to the Leeds Public Dispensary.
- KEYWORTH, J. W., M.D., M.R.C.S.E., Medical Officer and Public Vaccinator for the Aston Road, or No. 1 District of the Aston Union.
- LLOYD, E. J., M.B., House Surgeon and Secretary to the Denbighshire Infirmary, Denbigh.
- M'GILL, A. F., M.R.C.S.E., a Surgeon to the Leeds Public Dispensary.
- MACGATH, J., M.D., has been recommended for appointment as a Physician to the East London Hospital for Children and Dispensary for Women.
- RONALDSON, T. R., M.B., C.M., a House Surgeon to the Edinburgh Royal Maternity Hospital.
- URQUHART, A. J., M.B., C.M., a House Surgeon to the Edinburgh Royal Maternity Hospital.
- YOUNG, Mr. J. (Public Analyst for the Borough of Leicester and the Counties of Leicester and Rutland), Public Analyst for Northamptonshire.

Marriages.

RUTHERFORD-MORRISON.—On the 28th ult., in the Methodist Church, Ballymote, by the Rev. John Oliver Park, brother-in-law of the bride, Robert Acheson Rutherford, M.D., Manorhamilton, to Lily, second daughter of Mr. Robert Morrison, the Rock, Ballymote.

Deaths.

- ATKINSON.—On the 1st August, Robert Atkinson, L.S.A.L., House Surgeon to the Hull and Sealecoates Dispensary, aged 78.
- DURHAM.—On the 4th August, at Sandford, co. Dublin, Andrew Durham, Esq., M.D., Deputy Inspector-General of Hospitals, late her Majesty's Bombay Army, aged 61.
- FERGUSON.—On the 6th August, at Prospect, Mullingar, Joseph Ferguson, M.D., aged 73.
- HOWATT.—On the 16th July, H. R. Howatt, M.D., of Cumberland Street, Glasgow.
- NORTON.—On the 1st August, at Nantglas, Llanelly, Carmarthenshire, John Howard Norton, M.D., aged 59.
- RIX.—On the 17th June, on board the Royal Mail Steamship *Nile*, off Greytown, Central America, Rich. Avery Rix, M.R.C.S.E., late Medical Officer to the Chontales Consolidated Mining Company, Nicaragua, aged 31.
- SCHLESINGER.—On the 29th July, B. M. M. Schlesinger, M.R.C.S.E., House Surgeon of St. Mary's Hospital, aged 21.
- TRAILL.—On the 21st July, at Stromness, Orkney, William Traill, M.D., aged 43.
- WILSON.—On the 17th June, John Wilson, M.D., Surgeon R.N. (retired list), of Park Crescent, Brighton.

Advertisements.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM, 315 Oxford Street, London, W.—The office of the General Medical Council and of the Branch Council for England has been removed from 32 Soho Square, to the above address.

July 9th, 1874.

FRANCIS HAWKINS, M.D., Registrar.

THE CANCER HOSPITAL, LONDON, (Founded 1851). There is a VACANCY at this Hospital for a RESIDENT HOUSE SURGEON and REGISTRAR. Candidates must be unmarried, registered Members of the Royal College of Surgeons of England, and thoroughly conversant with the use of the microscope. The Honorarium 100 guineas per annum, with Board and Residence. Applications with Diplomas and Testimonials to be addressed to the Chairman of the Weekly Board, 167 Piccadilly, W., on or before August, the 27th next.

ROYAL FREE HOSPITAL, GRAY'S INN ROAD. There is a VACANCY for a JUNIOR HOUSE SURGEON to this Hospital. Candidates, who must be possessed of a Medical or Surgical qualification from one of the Examining Boards of the United Kingdom, are requested to send in their Testimonials to the Secretary, on or before WEDNESDAY, 19th AUGUST. The appointment will be made for six months only, but the holder will be eligible for re-election. Board and residence are provided in the Hospital.

JAMES S. BLYTH, Secretary.

OWEN'S COLLEGE (MANCHESTER ROYAL) SCHOOL of MEDICINE.—The WINTER SESSION will commence on the 1st OCTOBER. The Registration of Students will take place in the New School (Coupland Street entrance), on the 1st, 2nd, and 3rd October, from 9 to 11 a.m., and the registration will be continued up to the 14th October.

A composition fee of £48 in one payment, or in two payments of £25 each, which may be paid with an annual tutorial fee of £2 2s., admits to the complete course of study at the School; and a further sum of £42 to the Hospital Practice at the Royal Infirmary.

Prospectuses will be forwarded on application.

J. HOLME NICHOLSON, Registrar.

WESTMINSTER HOSPITAL MEDICAL SCHOOL, Opposite WESTMINSTER ABBEY.—The SESSION 1874-5 will commence on THURSDAY, OCTOBER 1st, with an Introductory Lecture by Dr. POTTER. The Address will be followed by the Distribution of the Prizes, and a Conversation in the Board-room. The new Physiological Laboratory will be completed by October 1st. The Examination for the Entrance Scholarship will be held on the 2nd and 3rd of October.

GEORGE COWELL, Dean.

5th August, 1874.

ST. THOMAS'S HOSPITAL, ALBERT EMBANKMENT, WESTMINSTER BRIDGE, S.E.

The MEDICAL SESSION for 1874 and 1875, will commence on THURSDAY, the 1st OCTOBER, 1874, on which occasion an ADDRESS will be delivered by Mr. MACCORMAC, at Two o'clock.

Gentlemen entering have the option of paying £10 for the first year, a similar sum for the second, £20 for the third, and £10 for each succeeding year; or, by paying £105 at once, of becoming perpetual Students.

Private Classes for Students preparing for Matriculation, and for the Preliminary Scientific Examination of the University of London, or for other Examinations, are conducted by members of the Staff, and embrace instruction in Chemistry, Natural Philosophy, Botany, and Comparative Anatomy. These Classes can be attended without entering at the Hospital.

PRIZES AND APPOINTMENTS FOR THE SESSION.

THE WM. TITE SCHOLARSHIP, founded by the late Sir Wm. TITE, C.B., M.P., F.R.S., the proceeds of £1,000 Consols, tenable for three years.

First Year's Students. WINTER PRIZES—£20, £15, and £10. SUMMER PRIZES—£15, £10, and £5.

Second Year's Students. WINTER PRIZES—£20, £15, and £10. SUMMER PRIZES—£15, £10 and £5. The DRESSERSHIPS, and the CLINICAL and OBSTETRIC CLEARSHIPS.

Third Year's Students. WINTER PRIZES—£20, £15, and £10. Mr. GEORGE VAUGHAN'S CHESELDEN MEDAL. THE TREASURER'S GOLD MEDAL. THE GRAINGER TESTIMONIAL PRIZE. THE TWO HOUSE PHYSICIANSHIPS. THE TWO HOUSE SURGEONIES. THE RESIDENT ACCOUCHERSHIPS. TWO MEDICAL REGISTRARSHIPS, at a Salary of £40 each, are awarded to Third and Fourth year's Students, according to merit.

The SOLLY MEDAL, with a Prize of at least 10 Guineas, will be awarded at the end of the Session, to a Student of the Third, Fourth, Fifth, or Sixth years, for the best Report of Surgical Cases.

MEDICAL OFFICERS.

HONORARY CONSULTING PHYSICIANS.—Dr. Barker and Dr. J. B. Sedon Bennett.

HONORARY CONSULTING SURGEON.—Mr. Frederick Le Gros Clark.

PHYSICIANS.—Dr. Peacock, Dr. Bristowe, Dr. Clayton, Dr. Murchison.

OBSTETRIC PHYSICIAN.—Dr. Barnes.

SURGEONS.—Mr. Simon, Mr. Sydney Jones, Mr. Croft, Mr. MacCormac.

OPHTHALMIC SURGEON.—Mr. Liebreich.

ASSISTANT PHYSICIANS.—Dr. Stone, Dr. Ord, Dr. J. Harley, Dr. Payne.

ASSISTANT OBSTETRIC PHYSICIAN.—Dr. Gervia.

ASSISTANT SURGEONS.—Mr. F. Mason, Mr. H. Arnott, Mr. W. W. Wagstaffe.

DENTAL SURGEON.—Mr. J. W. Elliott.

ASSISTANT DENTAL SURGEON.—Mr. W. G. Ranger.

RESIDENT ASSISTANT PHYSICIAN.—Dr. Turfot.

RESIDENT ASSISTANT SURGEON.—Mr. McKellar.

APOTHECARY.—Mr. R. W. Jones.

MEDICINE.—Dr. Peacock and Dr. Murchison. SURGERY.—Mr. Sydney Jones and Mr. MacCormac. GENERAL PATHOLOGY.—Dr. Bristowe. PHYSIOLOGY AND PRACTICAL PHYSIOLOGY.—Dr. Ord and Dr. John Harley. DESCRIPTIVE ANATOMY.—Mr. Francis Mason, and Mr. W. W. Wagstaffe. ANATOMY IN THE DISSECTING ROOM.—Anatomical Lecturers.—Mr. Rainey and Dr. W. Reid. PRACTICAL AND MANIPULATIVE SURGERY.—Mr. Croft. CHEMISTRY AND PRACTICAL CHEMISTRY.—Dr. A. J. Bernays. MIDWIFERY.—Dr. Barnes. PHYSICS AND NATURAL PHILOSOPHY.—Dr. Stone. MATERIA MEDICA.—Dr. Payne. FORENSIC MEDICINE AND HYGIENE.—Dr. Stone and Dr. Gervia. COMPARATIVE ANATOMY.—Mr. C. Stewart. OPHTHALMIC SURGERY.—Mr. Liebreich. BOTANY.—Mr. A. W. Bennett. DENTAL SURGERY.—Mr. J. W. Elliott. DEMONSTRATIONS MORBID ANATOMY.—Dr. Payne. MORBID ANATOMY AND PRACTICAL PATHOLOGY.—Mr. H. Arnott. MENTAL DISEASE.—Dr. Wm. Rhys Williams.

T. B. PEACOCK, M.D., Dean.

R. G. WHITFIELD, Medical Sec.

### LECTURES ON BRIGHT'S DISEASE,

WITH SPECIAL REFERENCE TO

PATHOLOGY AND TREATMENT,

DELIVERED AT THE ROYAL INFIRMARY OF GLASGOW,

By D. CAMPBELL BLACK, M.D.,

One of the Physicians to the Hospital.

#### LECTURE VI.

(Continued from page 105.)

GENTLEMEN,—In other cases true *tetanic* attacks occur, with opisthotonos and trismus. These cases are rare.

The convulsive form, then, comprises three varieties: the eclamptic, the local convulsive, and the tetanic.

*The Comatose Form.*—This form may either be the termination of the convulsive form, or may be of sudden accession, *sui generis*. It is *incomplete* or *complete*. It is in the last case that it is sudden, and of grave import. The face is pale; there is absolute insensibility. The pupils are sometimes normal, or sometimes dilated and sluggish under the influence of light. The patient is in a deep coma; there is stertorous breathing; and Addison has endeavoured to show that the stertor is differently produced from that existing in true epilepsy and cerebral apoplexy. In the latter he maintains that the stertor is caused in the nose and throat, while in the former it is caused alone by protrusion of the lips.

There is yet another distinctive character. The muscular relaxation and insensibility are general in uræmia, and not confined to one side, as they usually are in apoplexy and epilepsy. Furthermore, the uræmic coma is very insidious in its progress.

*The Mixed Form*, as its name implies, is a combination of the two preceding varieties; sometimes the *convulsive*,

and sometimes the *comatose* form predominates. Among the *rare types* are—1st. Those cases in which delirium constitutes a marked feature. Sometimes the delirium comes on as a complication in the convulsive form; but it may exist alone, and thus specially constitute this variety. At other times it comes on abruptly, or may be preceded by the usual premonitions of uræmia, cephalalgia, impairment of vision, obtuseness of intelligence, slowness of movement, &c. 2ndly. The delirium may be monotonous, distinguished by incessant low muttering. Or, 3rdly. *Maniacal*, in which the patient is in continual dread of being pursued, and appeals for succour. A very rare form still is the form where *dyspnœa* is a notable characteristic. This form, of course, must be distinguished from œdema of the glottis, a complication, as we have seen, not unfrequent in Bright's disease. The latter—that arising from œdema of the glottis—is usually of slow progress, and its intensity varies according to that of the localised *œdemæ* in other parts of the body.

The other form—the true dyspnoic variety of uræmia—comes on suddenly; it rapidly glides into the terminal coma, and causes death often in three or four hours. This condition is further characterised by a marked absence of physical signs of lung disorder corresponding to the difficulty of breathing. Christison has seen tracheotomy practised twice in cases of this kind, no trace of œdema of the glottis being disclosed.

On analysing the symptoms presented by uræmic convulsions, it is a fair and legitimate deduction that the variations presented depend on the particular portions of the cerebro-spinal axis affected. Thus, the eclampsia points to an excitation of the medulla oblongata; the tetaniform convulsions to a like impression on the cervical portion of the spinal marrow; the partial convulsions indicate an impression limited to particular nerves; the intellectual aberration indicates irritation, particularly of the surface of the hemispheres; and in the form where dyspnœa predominates it cannot be doubted that the part of the nervous system affected is the origin of the pneumogastric nerves, in the fourth ventricle; while, in the cases where the dyspnoic symptoms are complicated with sibilant respiration, it is probably the laryngeal nerves

that are paralysed, as aneurism of the aorta produces the same phenomena by pressure on the recurrent laryngeal.

**Diagnosis.**—The diagnosis of acute nephritis offers much less difficulty than that of the chronic form. The sudden occurrence of dropsical effusion into the peritoneum, the pleura, the pericardium, &c., with albuminous urine of high specific gravity, frequently containing blood, and febrile disturbance, are sufficiently characteristic. In the absence of albuminous or bloody urine—a circumstance rare in acute nephritis—the indications may be more equivocal.

The affection with which nephritis is most likely to be confounded is hæmaturia. It is to be distinguished from the latter by the following circumstances:—In hæmaturia fibrinous concretions, or even clots of blood, are usually found in the urine, and usually the renal region of one side is more tender on pressure than the other; the urine is generally voided with pain, and there is an absence of dropsy. Hæmaturia from contusion and renal calculi are not likely to be confounded with the bloody urine of nephritic urine.

In many acute diseases the urine may contain blood; but the history of the case, and the presence of clots and urates, clear up any uncertainty. In exceedingly rare cases, supervening on scarlatina, anasarca may occur without notable changes in the urine.

The *diagnosis of chronic nephritis* is attended with much more difficulty, and for the following reasons: Dropsy may be produced by other causes; the urine may contain albumen in conjunction with affections of the heart, liver, lungs—in short, owing to any condition which interferes with the free circulation of blood through the kidney. But when little or no pain is complained of in the lumbar region, when urine of a *light specific gravity* is passed containing no urates and a considerable amount of albumen, and no disease of any other organ exists which might account for the albuminuria, the diagnosis may be made with certainty. In the albuminuria from static congestion the specific gravity of the urine is almost always normal, the urea of the urine is not diminished, and the presence of albumen in the urine may be said to be capricious, depending, as it does, on the position of the body; thus, it may entirely disappear if the recumbent position be observed. Diabetes is sometimes complicated with the presence of albumen in the urine. It is well known that in the diabetic condition of the blood and the elimination by the kidney of, to it, a morbid product, induces in it structural changes; but the presence of sugar in the urine is a sufficiently distinctive feature to prevent error.

The presence of pus in the urine, in such cases as pyelitis and cystitis, may be mistaken for albuminuria. When the urine contains pus it necessarily contains albumen, which is one of the ingredients of pus. The reaction of liquor potassæ and ammonia on urine containing pus, with the general symptoms, should be sufficient to prevent mistake on this point.

If, after a short interval, cerebral symptoms and vomiting, even without dropsy, take place; if the urine be of a light specific gravity; if there be an absence of indications of disease in any other organ—the existence of chronic nephritis is more likely, than a cerebral affection, as a primary disorder. This would be confirmed by a history of exposure to cold, alcoholic indulgence, and the existence of general dropsy even at a somewhat distant date. If, in addition to all these symptoms, anasarca, or effusion occur, the diagnosis is absolutely certain. The appearance of epithelial cells and casts does not *immediately* bear upon diagnosis, as we have seen that they occur coincidentally with other diseases. But should hypertrophy of the heart, with valvular insufficiency or, disease of the liver, be present, the diagnosis is rendered yet more difficult. In such cases, moreover, the urine is sometimes of lighter specific gravity than it is in health, and it not unfrequently contains albumen. How are we to determine that the renal affection is primary, not secondary? Or may not the albuminuria be dependent on the simultaneous co-

operation of the two causes? As a rule, dropsies dependent on affections of the heart usually begin in the inferior extremities, and disappear during the observance of the horizontal position; dropsies dependent on renal affections generally begin in the face, giving to it a characteristic puffiness which the experienced eye so certainly recognises as not usually to confound it with any other condition. It is rare that the dropsy is so general in cases of simple affection of the heart, as when complicated with cachectic nephritis. In the dropsy due to affection of the liver the urine is usually scanty, of a dark, *bilious* colour, ascites is specially characteristic, and albumen is absent from the urine. In cases in which affection of the liver and kidney are concomitant, while it may be difficult to say to what extent either contributes to the production of dropsy, the affection of the kidney is recognised by the low specific gravity of the urine, and its contained albumen.

Dr. Noel Guéneau de Mussy (*Union Médicale*) remarks that in cases of what he terms “latent albuminuria” albuminuria develops itself silently, and is accompanied neither by anasarca nor by derangements of vision. Often its existence is overlooked until irremediable.

Slight albuminuria may exist for years without causing severe affection of the health. Latent albuminuria, like diabetes, is in many cases an arthritic dyscrasia, and is often preceded by uric gravel. Urates of soda is found in the tubuli, and the secretory cells are atrophied.

Dropsy following intermittent fever is of two kinds: the one depends on pathological changes in the kidney, and the urine is more or less albuminous; in the other the urine does not contain albumen, and no satisfactory reason of its occurrence has been given. It is usually curable by quinine and other febrifuges.

Of the dropsy which occurs in leucocythæmia explanation has already been given.

#### *Tests for Albumen in the Urine.*

1. Whenever the urine contains any substance coagulable by heat and by nitric acid, and *not* precipitable by acetic acid, that material may be affirmed to be albumen, for we know of no other substance which presents these characteristics.

2. The albumen so distinguished may be derived (a) from blood, (b) from pus, (c) from chylous urine.

3. The presence of blood is proved by microscopical examination; but frequently the blood corpuscles do not present their characteristic appearance. If the urine be acid, they retain their appearance for a long time, being only a little jagged at their borders; more frequently they are distended, and of a spherical form. Their colour is lighter than usual, they present a sufficiently well-defined outline, but they do not adhere in the usual manner. If urine containing blood be allowed to stand in a conical glass, the blood deposits, and may be recognised by the naked eye. If the sediment be filtered from the supernatant fluid, the latter is found to contain albumen. But if the microscope should fail to discover the presence of blood, chemical tests must be resorted to. Should the blood corpuscles be dissolved, they give to the urine a reddish-brown colour. If acetic acid be added to such urine, and the whole heated, a reddish-brown coagulum is obtained, which, on drying, becomes almost black. If this coagulum be dried, powdered, and treated with alcohol containing sulphuric acid, the fluid becomes reddish or reddish brown, owing to the presence of hæmatin; and if the mixture be evaporated, an ash is obtained which contains iron, whose presence may be demonstrated by appropriate tests. In testing for hæmatin, Hiller boils the urine, and adds to it concentrated caustic potash. Any albumen which may have been precipitated is thus dissolved, and the fluid becomes of a bottle-green colour, owing to the formation of a ferrous hydrate. Further boiling causes a precipitation of the earthy phosphates, with which precipitate the hæmatin is incorporated, yielding a reddish-brown or blood-red colour. The presence of pus is demonstrated likewise by microscopic examination, and by the addition of either liquor potassæ or ammonia,

which causes the urine to become viscid and jelly-like. Chylous or fatty matter is recognised by the addition of sulphuric ether, whereby the urine is instantly rendered transparent.

4. If the urine be alkaline when it is voided, or neutral and become alkaline, it is not usually precipitable by heat, and the neutralisation of it by an acid does not necessarily impart to it this property.

5. If a drop or two of nitric acid be added to albuminous urine intentionally or accidentally, coagulation by heat is prevented; but the precipitation, with or without heat, is brought about by the further addition of nitric acid.

6. The mere precipitation of urine by heat does not necessarily indicate the presence of albumen, for the precipitate may consist of phosphates; hence, to eliminate this source of fallacy it is necessary, *previous* to boiling, to add nitric acid, which dissolves the phosphates.

7. Phosphoric acid, either in small or large quantity, does not cause opacity of the urine, but it prevents coagulability by heat.

8. Acetic acid does not precipitate albumen either in large or small quantity, and when little is used it *does not* prevent coagulability by heat; but in larger quantity the urine remains perfectly clear even at the point of ebullition. In all these cases, however, the urine is coagulable by nitric acid.

9. Hydrochloric acid in small quantity does not precipitate albuminous urine, but it prevents its coagulability by heat.

10. Sulphuric acid, neither in small nor large quantity, precipitates albumen when the urine is cold. On being boiled it becomes opaque, but less so than if it contained no sulphuric acid.

11. Urine that is highly acid and free from extraneous intermixture is not always coagulable by heat. This, according to Bence Jones, happens when urine contains free hydrochloric or nitric acids in such quantity as to form a compound with the albumen, which is soluble both in cold and boiling water.

12. Nitric acid, added to concentrated urine, may cause a precipitate of nitrate of urea, but the microscopic appearances—even the naked eye appearances—are such as to obviate mistake. Or uric acid and urate of ammonia may be thus formed: The latter is dissolved in an excess of the nitric acid; not so the former—at least, except with a large excess of acid. Here, again, appeal must be made to microscopic characteristics. But the urine may contain these salts in *common with albumen*. Then the presence and proportion of uric acid and urate of ammonia are determined by the addition of acetic acid, which does not precipitate the albumen; and by heating, the urate of ammonia is dissolved and coagulates the albumen.

13. It is alleged that when albumen is in small quantity an excess of nitric acid by its oxidising influence may decompose and dissolve the albumen. This is a statement of questionable accuracy.

14. Nitric acid causes turbidity in urine containing turpentine, copaiba, cubeba, &c., but heat has no such influence.

15. Having guarded against all sources of fallacy, the most accurate test for albumen is the following:—Take a little concentrated nitric acid; into the urine to be tested, and contained in a test tube or champagne glass, let a little of the acid trickle down the side of the vessel. Admixture of the fluids does not instantly take place. The urine floats on the surface; the acid is underneath. Usually at the point of contact an intensely red, violet, or blue ring forms—the reaction of uroxyanthine. Should the colour be green, bile pigment may be present; but if albumen, a circular and well-defined turbidity succeeds, and the flaky material gradually sinks to the bottom. Should the urine be also rich in urates, a turbidity may also be thus formed; but then the albuminous ring is lower than the one due to the urates, and separated from it by a clear ring, and the latter gradually vanishes towards the surface, while the former subsides. The application of heat, however, dispels all doubt,

Other tests, such as alcohol, corrosive sublimate, tannin, alum, and carbolic acid, have been used for the detection of albumen. Alcohol, it is true, causes an opacity of albuminous urine; but it has the same effect on urine containing mucus. Besides, alcohol thus added has a greater affinity for the water than for the salts in the urine, and the latter are thus precipitated.

Tannin not only precipitates albumen, but likewise mucus and other constituents of the urine.

Corrosive sublimate, in like manner, seldom fails to precipitate urine whether it contains albumen or not, being decomposed by the sulphates, phosphates, and the organic matters of the urine.

Alum is likewise, and for similar reasons, untrustworthy for the detection of albumen.

Tidy's test consists of equal parts of carbolic and acetic acids. I am not aware that it possesses any special advantages over the ordinary tests in common use.

Dr. Brown-Séquard (*Archiv. of Scient. and Pract. Med.*), in referring to the fact that, while in certain cases, heat alone will not cause the coagulation of albuminous urine, and that in the *majority* of such cases the reapplication of heat after nitric acid has been added a precipitation of albumen takes place, infers that in such cases there must be a modification of albumen, which, so far from being coagulated by heat, actually is deprived of its coagulability by boiling.

In cases of purpura albumen is sometimes found in the urine; but here, unlike what obtains in chronic nephritis, the proportion of urea and of salts is either natural or greater than in health.

In many other acute diseases albumen may be occasionally found in the urine; for example, in acute rheumatism, peritonitis, and typhoid fever, more especially when the diarrhoea is profuse. The albumen, however, in these cases is far from being so abundant as in chronic nephritis.

When urine contains much mucus and is only slightly albuminous, and this coincides with the existence of pain in the track of the ureters, extending to the kidneys, this may be usually ascribed to acute inflammation of the mucous membrane of the calyces, of the pelvis, or of the ureters (pyelitis), and not to inflammation of the proper substance of the kidney. If the above should be complicated with nephritis, then dropsy is most ordinarily present.

Abscess of any portion of the urinary canal will cause purulent and albuminous urine. The microscope will distinguish pus globules, and alkalies give their characteristic reaction.

Urine containing semen is occasionally rendered opaque by the application of heat and nitric acid, like urine slightly albuminous. The microscope will reveal the presence of seminal animalcules, whose appearance are characteristic.

(To be continued.)

## REMARKS ON THE USE AND ABUSE OF SPIRITS AND FERMENTED DRINKS IN ARMIES DURING WAR.

By Surgeon-General C. A. GORDON, M.D., C.B., &c.

THAT the abuse of spirituous and fermented drinks in the army of Britain, as well as among the population of the country, is an immense evil, is a fact generally acknowledged and deeply deplored by all who take an interest in the well-being of the masses. I but repeat an accepted truism when I state that in their immediate and more distant effects such beverages, when improperly or over-indulged in, produce to a greater extent than any other single cause not only physical injury to the individuals concerned, but much of the crime against society, ruin to the subjects of the vice, inherited disease and

moral degradation to their descendants. All this is readily and most fully granted. To the army surgeon, however, the question presents itself, Is their use in suitable quantities and at proper times necessary or beneficial? Unhappily, the fair discussion of the question in this country is surrounded by difficulties. The subject has become one of party, not only among society, but among periodicals. Unless, upon the one hand, a man declares himself a *total abstainer*—that is, an abstainer from all such drinks, or, on the other, as an advocate of them, in which case he is himself apt to attract the look askance of the *very good*—he has difficulty in obtaining a hearing. Some journals would seem to be in the interest of one party or the other, so that a tolerably fair summary of what has been written on the subject is among the existing desiderata. In armies and nations the most ancient, as in those the most modern, the abuse of strong drinks has ever been a source of evil, for which no effectual remedy has even yet been found. In former times, as at the present day, however, the circumstance of evils arising from the abuse has not altogether obliterated the fact that under particular circumstances they are not only innocuous, but may become valuable means in the preservation and restoration of health. A recent French writer (a) expresses himself thus in regard to alcoholic drinks in the army: "Taken in limited quantities, they affect the economy by producing a general stimulation, for the most part agreeable. In the military *régime* they find their indication, especially in active service, when the exertion demanded exceeds the limits of disposable strength. They are also suitable when it becomes necessary to give a stimulus to the organism to withstand cold and wet." He observes, however, that "the nervous system of natives of the north being little excitable, the use of spirits is thus *perhaps* rendered necessary by them; but with more southern nations, especially the Latin races, whose nervous system is more readily deranged, alcoholic excitation is less necessary. The latter can only make use of them as a temporary spur." "Alcohol is not directly a source of strength; its prolonged use becomes a source of weakness, because the nervous system becomes deranged by successive excitations, then falls into a state of torpor from which it becomes no longer capable of recovering. On the other hand, the local irritation of alcohol upon the mucous membranes of the digestive organs destroys their functions, the sense of hunger becomes blunted, nutrition is impoverished, and the whole organism falls into a state of *marasmus*." M. Morache goes on to describe two forms of alcoholic intoxication—"the acute, or that brutal drunkenness that is known to everybody, and the chronic, which does not always follow from a series of acute fits of intoxication, but becomes gradually established in those who, although rarely guilty of excess, yet consume in some shape or other a greater quantity of alcohol than their system is capable of supporting." If a person in such a state is attacked by illness, or meets with an accident, the powers are ill-prepared to withstand either, so that recovery is retarded, or does not take place. Thus it is that men in the army, strong and vigorous in appearance, succumb to what would otherwise have been a slight morbid cause. As a rule, this author declares that alcoholic drinks, under the form of *eau de vie*, ought not to enter into the daily ration of the soldier, whom it brutalises and kills; but he adds: "Wine, with which (France) is so abundantly endowed, in which alcohol, sugar, and mineral salts are combined by the power of Nature in a manner which the chemist is unable to imitate," may be so allowed.

So great have been the evils that have arisen from the abuse of alcoholic drinks in the French army, that from the time of the elder Larrey downwards constant endeavours have been made by medical officers to encourage the substitution of coffee for these beverages, and there is some reason to believe that their endeavours have been

more successful than those of their brethren in the same direction on this side of the Channel. Without doubt, its universal adoption would be a great boon to all armies, and the great benefits obtained from it under particular circumstances are willingly allowed. It acts as a restorative stimulant after fatigue, is at all times a refreshing beverage, and is extremely valuable as a protective against malaria. The French vaunt its great virtues in preserving the health of the soldier in numerous campaigns, including those in Egypt, Algeria, the Crimea, Italy, and Mexico, and M. Morache speaks with satisfaction of the fact that in Paris the troops are more and more becoming to adopt its use as a substitute for spirits. But that there may be exceptional circumstances on active service in which the use of spirits may be necessary is allowed on all sides; that there are such circumstances is well known by all who are practically acquainted with war. As regards wine, its value as a remedial agent in many diseases is beyond question; that it is a prophylactic against diseases of various kinds is equally allowed, and that in times of great scarcity of food it of itself to a certain degree supplies nutriment is a recognised fact by persons who have themselves been subject to such conditions, as during a severe siege. "For fatigue, rest and food are the proper remedies. Alcohol given alone under such circumstances can only stimulate the already exhausted heart to fresh action." Thus a learned professor (a) expresses himself; but it may be said in reply that to stimulate the heart to fresh action is to stimulate the functions of other organs also, and thus to enable the system to recover from a state of depression that might itself be dangerous or fatal, and in which the ordinary causes of disease are in a peculiar manner apt to affect the individual. Dr. Parkes (b) gives a formula for the administration of wine or spirits to soldiers under certain circumstances, as after a fatiguing march, or when they are obliged to engage an enemy without sufficient rest or food. He advises two ounces of red claret wine with two teaspoonfuls of Liebig's extract in half a pint of water, or, if wine is not available, and it can very seldom be available on service in sufficient quantity on account of its bulk and difficulty of carriage, half an ounce of brandy or rum would be a good substitute. I have never actually tested the fact, but am inclined to think that claret, water, and Liebig's extract would be unpalatable in itself, and well calculated to make a man sick; with rum or brandy the effects would be scarcely less unpleasant, but I question very much if the British soldier could be got to swallow such a mixture. M. Morache (c) observes, in regard to the various extracts of meat that bear the name of the illustrious chemist, that even as soup they are little agreeable to the taste, and insipid; while, in large quantities, they have a salt flavour, and exhale an animal, or even a cadaveric odour. What, then, must these extracts be when mixed with cold water? But, continues M. Morache, not only is the extract of meat itself not nutritious, but taken in large doses it becomes poisonous. Such products, he observes, have not, so to speak, any nutritive value; they may, however, be useful to the economy, by the slight excitation they cause, and the activity they produce in the functions of digestion; but it would be a great error to introduce them into the ration of the soldier in a campaign, seduced by their facility of transport. In a *brochure* recently issued by one of the companies for manufacturing such preparations it is frankly acknowledged that the extract is only nutritive in the sense in which tea or coffee are so, and with all due deference to those who vaunt them, I would myself prefer to prescribe spirits with tea or cold water to giving them mixed with extracts described as insipid, cadaveric, innutritious, and toxic. It is something to note, however, considering the general tenor of opinions expressed, that the propriety of giving stimulants to soldiers under special circumstances is allowed by so high an authority as Dr. Parkes, for with very few ex-

ceptions writers and speakers confuse, or insufficiently distinguish, between the great evils that arise from abuse, and the unquestionable benefits that are obtainable from the use under certain circumstances of stimulating beverages. Because drunkenness and crime follow from excess and abuse of spirits, therefore spirits are to be altogether condemned under all and every circumstance! Here is an example of the manner in which the subject is at the present day discussed: "If there be any point of military hygiene that may now be regarded as settled beyond doubt or cavil it is this, that spirits"—"are hurtful to the marching soldier everywhere I believe, but nowhere more so than in hot climates." True, so far, no doubt; in one respect beyond the truth, in another short of the whole truth. And why this wholesale condemnation? Because, on the occasion of the siege of Delhi, (a) "vast quantities of spirituous liquors fell into our men's hands. Drunkenness became fearfully rife, entailing with it increased sickness as well as relaxation of discipline." "We all know the stake played for at Delhi. It was the empire of India. Mark how alcohol put the issue in peril." Therefore, because such gigantic evils follow upon the unrestrained abuse of a powerful therapeutic agent, its use everywhere and in all circumstances is to be forthwith suppressed!

The fact is, that wines and other strong drinks have everywhere and in all times entered very largely—often far too largely—into the beverages of the soldier, and in all probability will ever do so. Yet, as there are reasons for most things, so there may possibly be for this condition of matters. Let us briefly follow to some extent its history. Among the nations of antiquity wine formed an important item in the daily ration of the soldier. In Greece the land and sea forces lived for the most part upon bread soaked in wine and oil. In the armies of Rome the very excellent plan was followed of issuing to the troops a ration of wine and one of vinegar on alternate days; nor have the marches performed by these troops under great vicissitudes of climate and other conditions been yet exceeded. With regard to our own army, excesses not only in drink, but in other vices, were probably more general in former times than they are in the present; at all events they were looked upon as inseparable from military life, although condemned and deplored quite as much as they are now. There seems, however, to have been this difference between the former manner of treating the subject and the present, that while excess and abuse were condemned, the use of the beverage in moderate quantities was sanctioned, doubtless because certain advantages were observed to follow the practice, and it would be well if now in articles on the subject an equally distinct line were drawn between the evils that arise from beastly indulgence in and the benefits to be obtained from moderate and proper use of these beverages. In 1424, when our Henry the Fifth was advancing upon Troyes, he issued various sanitary regulations for his troops, one of which directed that they should temper their ration of heavy country wine with water. In 1475, when the English army entered Amiens, the troops appear to have been right royally treated: Louis the Eleventh caused tables to be set in the streets, and the soldiers to be entertained. According to the chronicle of the event there was great plenty of wine, and an abundance of servants to wait upon them; and it is further related that on the occasion "not a drop of water did they call for." I turn now to my fellow Highlanders, and note what they were wont to do in "the good old times." In 1528 the Scottish army which assembled at Braemar was decidedly well provided with creature comforts; among supplies laid up in that place for their use we read that there was plenty of good ale, sack, claret, tenter, elegant (Alicante), "with some most potent aqua vitæ," in other words, doubtless the real peat reek—usquebeadh. Between 1558 and 1603 the soldiers of the army of "good" Queen Bess had a daily scale of rations that would make a sanitary reformer of the present day stand utterly aghast; but in addition they enjoyed an

allowance of strong drink that would completely dumfound him. Those who were specially raised to resist the threatened Spanish invasion had, if belonging to the infantry, two quarts of beer and a quart of wine daily, and if to the cavalry a still more liberal allowance. Fortunately, in more respects than one, events did not occur to test the equitation of the brave dragoon of the period. Possibly their allowance was much beyond what was good for them. Doubtless, however, there were reasons, if not hygienic, at all events of policy, why so great a liberality was exercised. The forces of Charles the First had also a stated quantity of spirits as part of their daily ration, and we read that in 1642 they lodged a formal objection against the inferior quality of that issued to them. In 1689 the soldiers of James the Second in Ireland were reduced to great straits, not only in regard to food, but, as we learn, in regard to their allowance of "drink;" even the guests at the royal table had their bread and wine measured out to them, and everybody else in the force "drank detestable beer." At a later period of the seventeenth century, the troops of William of Orange who occupied the fort near Inverness that has since then borne his name, had among other supplies "brandy in somewhat superabundant quantities." Subsequently, from the time the army was placed upon a permanent footing, the soldier had as part of his daily ration an allowance of French wine during the short interval that intervened between that date and the treaty of Lisbon, under which a check was put upon the free importation of light wines.

Sir John Pringle laid considerable stress upon the good effects obtained from the moderate use by the troops of wines and other strong drinks. He makes frequent mention of wine as a preventive of scurvy and malignant fever, both of which diseases prevailed extensively in the army operating in the Low Countries in 1742. To some of the men out of hospital he prescribed Rhenish or French wine, of which, he tells us, (a) some men consumed near a quart per day, and part of that undiluted. As to diet, he further remarked: "It may be observed that hopped beer, wine, and spirituous liquors coming into general use have been a great means of suppressing putrid disease;" and in reference to the improved dietary introduced by him, including these drinks, vegetables, and the use of tea, he continues: "How far all these things may be abused is not now the question." Unfortunately more recent writers seem unable to draw the distinction that Sir John Pringle defined. In 1764 Dr. Donald Monro, an army surgeon of no less reputation, published a valuable work upon "Army Diseases and Military Hospitals." In that work, among other excellent hygienic instructions, we read that troops "should be well supplied with fresh vegetables of different kinds, as well as with beer, cider, or wine." He recommends the use of spirits "in moderation," adding that "in winter, when the weather is very cold or wet, a glass of brandy, or of the spirituous tincture of bark, given to the men as they went on duty, and especially in the night, has been found of great use." In 1791 Dr. John Bell deprecated the extent to which drunkenness prevailed among the troops in the West Indies; he inveighed also against the system of the day, according to which no less than half a pint of rum was issued to each man daily. While quite alive to the evils caused by such a system, he was far from suggesting a system of total abstinence, knowing well that such a system was alike unsuitable and impracticable. He recommended that beer or wine should be issued in lieu of spirits, adding with regard to the latter, that wine "is one of the best preservatives of health, and that it should be distributed to the healthy troops on different occasions." In 1799 Dr. Lemprière made some comments against the extent to which intemperance continued to prevail in those islands, and details the measures he in communication with his commanding officer took to repress it, as well as to advance the physical and moral welfare of the troops under his charge. He tells his readers that "when the funds of the regiment were good the commanding officer would give

(a) *Journal of the Royal United Service Institution, loc. cit.*

(a) "Observations," pp. 274, 284.

an occasional allowance of bottled porter to the men," that "care was taken that the allowance of rum was duly mixed with water, and that the men did not drink the whole of their quota at once before sitting down to dinner." He by no means recommended the withdrawal of all strong drinks; he merely laid down certain rules and instructions in regard to their use; and here I would observe, that although the labours of the older medical officers of the army are comparatively little known at the present time, their own writings testify that they studied the requirements of the troops under their charge quite as much and as carefully as their successors are capable of doing. If, therefore, they recommended the moderate use of fermented or spirituous drinks under particular conditions, we may assume that they had good grounds for that recommendation.

That such recommendation did not extend to all conditions is rendered sufficiently evident by the history of the Indian expedition across Egypt, the climate of which approaches that of Algeria, already alluded to. The force under the medical charge of Sir James M'Grigor was on that occasion debarred from the use of spirits during the hot season, but permitted to have a certain quantity during the cold. (a) Throughout the hot season a ration of Greek wine was daily given to the soldiers. It is to be noted that the summer climate of Egypt was then, as it still is, extremely hot and dry, altogether unlike that of Walcheren, where, a few years afterwards, Sir James and Dr. Borland inculcated the use of spirits as a sanitary precaution against endemic disease. In 1809 these two distinguished medical officers, in conjunction with Dr. Lemprière, drew up a series of rules for the preservation of health, among which we find it recommended that "in the evenings of the nights on which they mount guard an extra allowance of spirits to each man would be essentially beneficial," and that "when relieved the next morning a comfortable warm breakfast of strong coffee should be in readiness." Bearing in mind the fact also that Walcheren was extremely malarious, it is of importance to add the further recommendation that "the diet, especially in the sickly period, should be nutritive, and the broths well spiced with pepper;" also that during the same season "a small portion of unmixed spirits might be usefully allowed early every morning." Whatever may, according to the fashion of the present time, be said in regard to such a plan, it is unreasonable to suppose that the medical officers making the proposal had not well considered the subject, and saw good reason for the measure they recommended. In 1810 yellow fever recurred with great severity in Cadiz. Sir James Fells, who was principal medical officer there at the time, recommended such measures of a sanitary nature as appeared to him most appropriate; among them he suggested that each soldier should have a pint and a half of porter daily, and that those employed on night pickets, or other duty near the marshes should be allowed their ration of spirits. In 1821 Dr. Luscombe published a work on the preservation of health of troops on service from miasmatic diseases. Among the sanitary measures recommended by him were that "they should be well clothed, have liberal animal diet, a moderate allowance of beer, wine, or spirits, regular exercise, and cheerful occupation, but avoiding intemperance and fatigue." In India, so far back as 1831, the local government authorised the issue of light wines to the troops in lieu of spirits, in the hope of checking the fearful extent to which indulgence in more objectionable drinks prevailed among the white troops in that country, this measure having been chiefly due to the representations of Inspector-General Burke, who from 1827 had continued to urge his opinion that the ordinary spirit ration ought to be completely withdrawn. "I am quite willing to believe," so Dr. McLeod wrote in 1836, "that the unfortunate practice of Government issuing the dram had its origin in the best intentions, and from a mistaken idea of its effects on health; but it has long been known that spirits are prejudicial under most circumstances, and

under all unnecessary." (a) Neither of these medical officers, however, recommended "total abstinence;" their knowledge of the soldier and of the world was far too extensive for that: they did recommend, however, that properly regulated canteens should be established at which the men could obtain "wholesome wine and malt liquor." Here, again, drunkenness was one thing, the moderate use of "wholesome" wine and malt liquor another; and Dr. Burke was doubtless right when he wrote that "drunkenness, the besetting sin of the British soldiery, has hitherto resisted every attempt to keep it within bounds, and will most probably continue to do so until the soldier becomes a better-instructed man, until he imbibe some little portion of the improving spirit of the age, and hold a more elevated rank in the scale of moral and intellectual beings." The sentence was originally written in Calcutta, in 1827, but Dr. Burke was far in advance of his time. In 1834 the 13th Foot, then stationed at Cawnpore, was the first to supply coffee, tea, light wines, and groceries in the regimental canteen for the use of the men, the intention being thus to wean them from the vice of drunkenness. Tea or coffee was also given to the men in the early morning. Two years before, an attempt had been made at Meerut to introduce the use of beer in regimental canteens; a similar attempt was also made at Calcutta, and so favourable were the results in both cases, that not only did the vice of drunkenness decrease, but so did the prevalence of serious accidents, apoplexy, and delirium tremens. Good was at the same time effected in another way. The profits obtained in canteens afforded the means of benefiting the wives and children of soldiers. In some regiments temperance societies were constituted, the first year in which we read of their being established in India having been so far back as 1828. The first success attending them was very great, not only in diminishing sickness, mortality, and crime, but in enabling the soldiers to deposit larger sums of money in the regimental savings bank. Unfortunately, however, these excellent establishments did not receive from the Government of India the support they deserved; they for a time languished, and not long afterwards were absolutely forbidden by the Duke of Wellington. But better times were not far distant. Measures long urged by medical officers were reintroduced, and since then the authorities, Indian and Imperial, have shown the greatest willingness to adopt the views which formerly neither seemed to care much about following. What is of importance to note, however, is the fact that although these early "reformers" were fully convinced of the evils that arise from abuse of spirits and fermented drinks, and in reality laid the foundation of all that has more recently been done to wean the soldier from them, not one of them went so far as to recommend the complete deprivation of them.

It is sometimes asserted that during the war in Afghanistan the troops were altogether without spirits or strong drinks of any kind. What are the facts? The 13th Regiment occupied Jellahabad; the men were reduced while there to half their ordinary allowance of food, and completely deprived of the spirit ration to which in India they had been accustomed; they were for the most part severely worked in establishing defences against the enemy, and it is said enjoyed a degree of health previously unknown among them. Here it has been the custom to stop in the narration; but for the benefit of those whom it may concern, I continue it a little further. Dr. Robertson, surgeon of the regiment, turning his previous knowledge to account, extemporised a "still," prepared malt from grain, and thus distilled a kind of whisky, which, according to personal narratives, was highly appreciated by those to whom it was issued. We further learn that when in 1843 that regiment returned to India, the 35th Bengal Native Infantry entertained the men of the corps at dinner, and so careful were the Sepoys to meet all probable requirements of their white brothers

(a) "Public Health," by Dr. Guy, Part II.

(a) *Medical Times and Gazette*, No. 1007, vol. II., 1869.

that they provided a number of dhoolies and bearers to convey to their barracks such of their guests as might indulge too freely in the luxuries placed before them.

Since 1855 the use of beer in regimental canteens has been gradually encouraged, to the almost total exclusion of spirits. It is found in practice, however, that although the use of beer is in many respects less injurious than that of spirits, it is by no means without special evils of its own. When indulged in habitually, even to the extent obtainable in canteens, it stupefies and narcotises, predisposes to apoplexy, and affects injuriously the functions of the liver and kidneys. Under conditions of great fatigue, however, a draught of ale is in India, as elsewhere, not only grateful, but a direct restorative, supplying a want which in the case of very many persons can by no other means be met. Experience in India amply proves that exposure to the sun after free indulgence in beer is extremely dangerous; but that its moderate use after sunset, or after the work of the day is done, is, to those who can partake of it, both grateful and wholesome; in the case of those whose health begins to fail without the presence of any specific disease it is indispensable. Here, again, the distinction is drawn between the proper use and the abuse of the beverage. We must also observe, with regard to the issue of beer in canteens, that whatever may be said on the subject of abstinence, the soldier will, so long as he has the means and the power, indulge to some extent at least in strong drinks, and therefore, policy and sanitary considerations alike indicate the propriety of providing him with wholesome beverages in his own barracks instead of depriving him of the means of all indulgence there, thus driving him to haunts of vice and disease in surrounding villages.

During the operations connected with the Indian mutiny our troops were on occasions not only deprived of all spirits, but of all kinds of intoxicating drinks; they and their officers used only "cold" tea, if such a term is applicable to uncooled drinks in the intensity of the hot season. So far were all from suffering inconvenience, that they doubtless benefited from it, and it was observed that those who died by heat apoplexy during the summer months were those who had been previously habitual drinkers, or who had clandestinely indulged in a debauch previous to a march during the day time. In the rainy and cold seasons, however, there were occasions on which an allowance of spirits or beer was necessary for health, and beneficial. In 1865 a spirit ration was issued to the native Indian troops employed in Bhotan, and according to the testimony of medical officers with the expedition, with good results as regards health. In the expedition to Abyssinia spirits and fermented drinks were absolutely prohibited, the only beverages allowed being tea and coffee, and the results are stated by some of the medical officers who accompanied that expedition. Much of the food obtainable on that occasion is said to have been inferior in quality, and to have been imperfectly prepared. The consequence was that the digestive functions of the soldiers became impaired, derangement of the bowels prevailed to a great extent, the process of assimilation was imperfectly performed; nor did the men recover until on their return journey from Magdala they obtained a ration of spirits. According to some statements, spirits and all other ardent drinks were absolutely denied to the troops during the recent expedition to Ashantee; but what are the facts? It was found necessary, as a preventive against disease, to issue a ration of spirits to the men on the completion of the day's march. The prospect of obtaining it acted as an incentive to the men while on the road; the stimulus afforded by the spirit not only served as a temporary restorative to the system after great fatigue, but thus enabled it to "tide over" in a manner the period during which there was the greatest risk of attack by malarious disease in one or other of the various forms in which it existed. Let any person look over the files of the illustrated papers of that time also, and they will be able to form an idea how far some of the officers practised total abstinence whenever they had an oppor-

tunity of doing otherwise. Champagne was evidently in request on the Gold Coast, as in bygone days; nor can those who know practically what service in that part of Africa really is avoid mentally ejaculating "Small blame to them!" On this subject I would again refer to some of the most recent French writers on army hygiene. M. Bouchardat (a) observes with truth that eau de vie and absinthe are more hurtful than useful, and ought only to be issued exceptionally. Such exceptions are when soldiers are subjected to great fatigue, to enable them to tide over the period of depression from this cause when disease is most liable to make its attack, when food is insufficient in quantity, as during sieges, or imperfect in quality, as on expeditions like those to Abyssinia and Ashantee, where the supplies yielded by the country were inferior in kind. The abuse under such circumstances may increase the evils it is intended to counteract, but the moderate use of spirits or wine in such instances is recommended by hygienists. The same author further adds that in hot dry countries, as Algiers, spirits or eau de vie and absinthe are condemned, light wines being recommended instead, together with coffee for ordinary drink, coffee having also an effect in purifying water of inferior quality. All this is an almost verbatim confirmation of what has been said on the same subject by medical officers of our own army who have seen considerable service under the conditions related. One good suggestion of the French, however, ought not to be lost sight of. They observe that when circumstances demand that spirits shall be issued to the troops, the allowance to each man ought to be given with the coffee and sugar, and taken together.

(To be continued.)

## ADDRESS IN OBSTETRIC MEDICINE.

By J. MATTHEWS DUNCAN, M.D.,

Physician to the Royal Maternity Hospital, and Lecturer on Midwifery in the School of Medicine, Edinburgh.

### PUERPERAL PYÆMIA, ETC.

NOW-A-DAYS, as compared with even a quarter of a century ago, obstetrics have flourished and grown so rapidly that he who is called upon to give an address such as this cannot but feel embarrassed in the selection of the matters to which he would call attention. If he is not to present his audience with a mere catalogue of details, he must exclude great departments; if he is not to be a mere registrar and exponent of the opinions of others, he must further restrict the scope of his review.

At one time, and that so late as last century or early in this, the whole field of medicine could be with comparative ease occupied by one mind. The same man practised and also taught all its branches, medicine, surgery, and their subdivisions. If one man proposed to do this now we should look upon him as a foolish pretender.

Rarely, and at long intervals in the course of the ages, a powerful mind is produced, such as that of a Newton in physics, who, using the scattered knowledge accumulated by his predecessors, succeeds by his own discoveries and generalisations in restoring simplicity where before there was complexity, and in making for his successors a sort of royal road to the science of his day. But such a master-mind, while on the one hand it simplifies and builds by generalisation, does, on the other hand, increase complexity and number of incoherent details by stimulating progressive inquiry. We hope we shall never again see the return of those dark days when one man could dare to profess or to practise the whole science and art of medicine.

It is by division of labour that we secure growth, and it is vain to regret the feebleness of our powers. As each department of medicine grows, it is, like its parent stem, doomed to subdivision. He, however, who brings the

(a) "Annuaire de Thérapeutique," 1874, page 244.

widest attainments and the most varied talents to bear on his chosen branch, will, *ceteris paribus*, be the greatest in his department. But who is equal to the demands of any department? To tell the truth, there is not among us a single man who has mastered all the details and work of even one single individual topic. One finds the histology of his branch fully occupies his powers; another is similarly placed in regard to its chemistry; a third finds full occupation in its physical relations; a fourth, gleaning behind all these, finds his hands full in trying to be practically useful to his patients.

Partly as a result of the subdivision of labour, greater progress is being made now than at any previous period in the history of medicine; and there is no greater exhilarant and stimulant of enthusiasm than that very progress which is the result of well-judged zeal. In the field there is work for minds of every kind, for talents of every description; for him who truly observes and accurately notes details, for him who arranges or classifies, for him who experiments, for him who suggests and demonstrates conclusions, for him who confirms or overthrows by the process of verification. Every one of us should take some part in this work of advancing medicine, a more important part than that humble and useful one in which all should, in addition, take a share, the attentive listening to and applauding the diligent and the successful.

There can be no doubt as to what is the paramount cause of our more rapid progress in recent times. It is adoption of proper method; it is the modern attempt to found or still further to build up a science of medicine on what is known as the Baconian plan. Imagination and ratiocination are not even now excluded from the operations, but nothing is held as proved by mere reasoning, and when the philosopher strays far from the solid shore of rocky facts he loses his intelligent audience, who have no interest in his occupation of beating the air. The medical man proceeds nearly in the same manner as the physical philosopher. He observes by the naked eye, then by the microscope, and this instrument he aids by numerous experimental plans of hardening, cutting, tinting, and staining. He applies so far as possible physical laws to explain natural and morbid processes. He institutes new experiments to elicit truth. He makes the same appeals to chemical science, and to the practical chemist as he makes to physics and the physicist. He reasons on what he obtains, and tests the truth of his conclusions, verifying by further observations and further crucial experiments.

Everyone who knows the history of midwifery must admit that it is by these methods alone that progress has been made. The greater part of what has been attempted, and the greater part of what is being attempted, is not according to this method; and the labour is vain. The substantial progress, often seen at the time only by a few, and appreciated by a small circle, is achieved by scientific method, and is like the grain of mustard seed which grows and grows till it be a great tree. Obstetricians can justly boast that, in some departments, mere obstetrical knowledge is ripening into a science of obstetrics, a boast which happily some other subdivisional branches of medicine can truly make.

The first subject to which scientific obstetricians, as a matter of course, direct themselves, is natural labour in all its varied aspects; and it is in some parts of this that the greatest advances have been made. The great idea of "mechanism," so loudly proclaimed by Levret, is in process of being worked out. The first stages have been nearly completed by the writings of W. Hunter and Smellie, of Ould, Solayres, Saxtorph, and Nägele. But, now that their inquiries are completed, we are landed in a more difficult and higher stage of this investigation, a stage demanding much more than the good powers of observation and description which sufficed for the former. Standing side by side with contemporary workers at these outposts of science, we are not good critics of the comparative value of their works; but among them we may signalise names familiar to you all—Hecker, Kehr, Schröder, Poppel, Haughton, Schatz, Küneke, Schultze, and many others.

Schröder, Poppel, Haughton, Schatz, Küneke, Schultze, and many others.

The majority of practitioners, however, take far more interest in the management of morbid labour than in any other department of obstetrics; and this for the evident good practical reason that there lie the questions of the highest, immediate, most pressing urgency—there difficult cases and how to manage them—questions which, in the interests of the poor patients and of the anxious practitioners, brook no delay, which cannot wait for the slow decisions of science, however valuable these may be when at last they do come. But, even though science is not at hand to offer the solution of difficulties in practice, it is the duty of every obstetrician, with a view to the advantage of his confiding patients, to watch the progress of science, if not to contribute to it, as well as to select more or less empirically among modes of treatment. He should at once contribute to build up science, and at the same time be ready to meet in the field of practice the great difficulties that come in his way. Like the Jews of old, he should work with one of his hands in the permanent work, while with the other hand he holds a weapon wherewith to fight against Sanballat and Tobiah. He who directs his professional life after this manner will certainly be the best practitioner, the most useful to his immediate patients, and peradventure happily useful indirectly to the patients of all instructed practitioners in all coming time.

There is no department of obstetrics from whose scientific progress more is to be expected by the mere practitioner than that of morbid labour. This is a branch in which a great deal of valuable work has been expended with invaluable results, but much more still is required before we can style our practice rational or scientific. Morbid labour in contraction of the pelvis is a well-known and typical part of this practical department; and to permit brevity as well as to give point to our remarks, let us be supposed as referring to it alone meantime. Now, where is the practitioner to look for guidance in this matter? He can nowhere find a secure resting-place. What views is he to adopt as to mechanism? What treatment is he to pursue? What instruments is he to use? Whom is he to adopt as his guide—Collins, or Simpson, or Dubois, or Hodge, or Barnes, or Hicks, or Spiegelberg, or Schröder, or Leishman? He must act, and to the best of his judgment and ability. To decide among these able and ingenious but discordant advisers he is unable, and there is no hope of his being very soon in a position to do so. However dogmatically the teacher may write on these subjects, he settles nothing for any one but himself and his disciples. The elementary data necessary for arriving at conclusions on these subjects are not yet acquired; but they are being rapidly elaborated. When they are worked out, then there will be a vast diminution in the area over which there is at present mere difference of opinion; and many practical directions will flow from such knowledge which, not then resting on opinion, will command, nay compel, general consent.

To secure this position for the practice in contraction of the pelvis, there must be, first of all, a nearly complete view of the whole mechanism of natural labour, not merely of what is popularly called mechanism in our textbooks, and we know that we are very far off from this complete view. Then pelvimetry must be improved, and even uterine craniometry. Then the modes of progress of labours in contracted pelves of different degrees and kinds, and both when assisted and when unassisted, have to be made out. Then we have to study the explanations of these modes of progress. Then we have to accumulate experience and laboratory experiments of complexity and variety in order to discover what is the best direction of treatment. Then we have by similar means to find the tools best suited for effecting our varied purposes.

In every one of these departments, we are proud to say, most valuable labour is at present being expended, and light is being converged on this great practical matter—delivery in cases of contracted pelvis. Till this light

makes the subject clearer than it is at present, we can have no final adjustment of our differences and difficulties. Mere dogmatic empirical teaching must be allowed to prevail. We must, as people do in matters of politics and religion, choose our authorities and do our duty under them as we best can. It would be tedious to enumerate the names of men who have recently contributed to the progress of this subject; but, at the risk of making omissions which are to be regretted, we may signalise among foreigners Michaelis, Litzmann, Hecker, Kehrer, Dohrn, Spiegelberg, Olshausen, Fehling, Cohnstein, Pajot, Joulin Breisky, Braun, Martin, and Von Haselberg; and among ourselves Radford, Churchill, Simpson, Barnes, Hicks, Playfair, and Kidd.

After natural and morbid parturition come subjects of far more difficult investigation, natural and morbid puerperality. As their secrets are far more deeply hidden, so our progress in bringing them to light has been less and is more recent; yet it is made in a way strictly analogous, if not identical, with that which has conducted us to so much acquaintance with parturition. The steps of natural healthy recovery from childbearing are first investigated; and here much has been attained through the labours of Kölliker, Farre, Priestley, Robin, Friedlander, Turner, and many others. Then, in logical order, we come to morbid puerperality, the subject more immediately interesting to accoucheurs, one of the most important topics, not in obstetrics only, but in the whole of medicine, one which has been discussed with an excessive copiousness, but with very little advantage till recent times. There is in the whole large library of puerperal diseases not a work of considerable value before the early part of this century. We have to come down to the names of Dance and Cruveilhier, and Robert Lee, and Virchow, and Pasteur, and Sanderson, and Lister to find the indistinct bridlepath which is quickly becoming an evident broad and great line of beneficent scientific progress, a progress whose practical results will overflow, not obstetrics merely, but surgery also, and medicine proper. Old books on puerperal diseases are full of disjointed facts and mere discussions. It is only now, when we have resorted to statistics, to anatomy, and to researches by the microscopist and the chemist that our way clears up towards a comparatively full intelligence of the awfully important puerperal diseases. The old works of Puzos, of Willis, and of others are nearly as valuable as most of those of the last generation of authors. But since the times of phlebitis and lymphangitis began, this department has ceased to move in a circle of no progress, and almost every day we are reaping new increments of knowledge, not only valuable in themselves, but indispensable to still further advances.

In connection with this subject there is a preliminary inquiry whose importance is self-evident, and which, remarkable to relate, has only recently been discussed formally, and with sufficient means—the mortality in childbirth, or total mortality of childbirth and in childbed. How many women die from all causes during childbirth and in the puerperal state? Of course, such a question, lying on the surface, has been considered and answered, but the responses have been most insufficient and erroneous. The ordinary belief seems to be that there is, in connection with childbirth and lying-in, no mortality in a well-conducted practice. Miss Nightingale says that deaths from puerperal diseases ought never to arise after delivery in a properly-conducted and managed institution for lying-in women. In a late number of one of our principal medical journals appears a report of one of these properly-conducted and managed institutions. The hospital is a military one, and not a death is reported; and the article is evidently written with a view to show benighted civil obstetricians what is the result of a proper conduct and management. I have often heard sanguine medical men say that in the course of a long and large practice they had not had a single fatal case. Now all such beliefs, reports, and statements are mere incumbrances of the inquiry, and are to be thrown overboard, if not more ungracefully dealt with. We have no time to trifle with such nonsense, for

we are everywhere surrounded by awful deaths in childbirth and in childbed, where there has been, so far as can be discovered by ordinary mortals, nothing but proper conduct and management.

Another response to this great question is familiar to all; it is derived from Merriman, and has often been repeated, not only as evidence of the mortality of childbirth, but also to show the successful progress of obstetrical therapeutics by the rapid diminution of the maternal mortality. It requires such a stretch of credulity to place the slightest confidence in Merriman's tables, that I no longer regard myself as justified in taking up your time any longer with them. More recently, and on much higher, even on official authority, somewhat similar statistics have been proclaimed as evidence of the progress of obstetrical therapeutics from decade to decade; but, alas for us! the evidence will not bear inspection, and we shall not inspect it. Even now, in 1874, we are only striving to reach a sound conclusion as to this mortality; and after all our labour, official and private, have no statistics to be relied on for the comparison of the results of successive decades or of longer periods. The importance of the question needs no demonstration, and it must be solved in a scientific manner. We are seeking not what we fancy or wish, but what is. There can be no doubt that the death-rate does represent marriage and childbearing as a most perilous ordeal for a young woman to encounter; and it is not good reasoning to use this, as a great author has done, to prejudice us against receiving what may be proved. During the whole life, including intra-uterine existence, the female half of mankind has a great advantage over the male in point of mortality, except that for a considerable time childbearing brings her nearly to the level of the male; and that, for a less time, the risks of primiparity sink her below him. Childbearing is in these kingdoms the special, and, so far as known, the only special great cause of enormous increase of female mortality above what it would otherwise be. Primiparity produces a great exaggeration of the childbearing risks. It is this mortality that we seek to estimate, and you observe it is of the highest human interest; but it is for medicine of special importance, being a cardinal element in the solution of the question of the value of hospitals. These noble institutions, the lighthouses of practice, have had their reputations tampered with on the most insufficient grounds. If we are ignorant of what may be called the normal mortality of childbirth and lying-in, how can we justly judge the hospital mortality? If we do not estimate the excess of special, and, in a sense, just causes of mortality in hospitals over those acting in the country generally, how can we fairly measure the salubrity of maternities? It is impossible to do so, yet there has been a lamentable and injurious amount of such mere cavilling with institutions whose reputations should be too sacred for any but the most solemn and logical consideration.

Among the Chinese, puerperal mortality is held, according to Dr. Jamieson, to rise as high as from 1 in 12 to 1 in 20—an alarming and scarcely creditable statement; yet Dr. Thin, lately of Shanghai, believes it to be true. Some statistics of the city of New York, recently published by Fordyce Barker, yield a puerperal mortality of 1 in 35, a terrible result; and on the surely extravagant admission that a quarter or even half of the births were not registered, we have here a very high figure. Faye states the puerperal mortality of Prussia as 1 in 84; and that of Finland, according to Pippingskjöld, as 1 in 106; and that of Norway as 1 in 131. I found that in Edinburgh and Glasgow, in 1855, the mortality of married women within six weeks after delivery was 1 in 107 at least. From a large collection of data, and trying, however rudely, to get an approach to exactness, I estimated the mortality within four weeks after delivery as about 1 in 120.

Hervieux says there are places where for a long series of years this rate has not risen 1 in 1,000; but he must derive his information from some other planet than this, for certainly there is no such abode of the blessed known

among the inhabitants of this earth. Le Fort estimates the rate as 1 in 212; but his figures and reasoning are such as to render this determination unworthy of any reliance, as has been sufficiently demonstrated. Farr has carefully estimated this rate, and arrived at the conclusion that it is 1 in 190. But, however much we may be disposed to bow to his authority, we are bound to scrutinise his method; and, on doing so, it turns out to be very unsatisfactory. He is dealing with a system of registration which is not compulsory; he seeks to verify the returns relied on by appeal to the returners, which is something like trying to correct an error by itself; he made no independent search for the deaths of the delivered women; he made no correction for twins, nor for still-births. On all these accounts I regard his result as being not only out of keeping with the best of the others, but as not especially reliable. The data of foreign countries which I have given may be very good for aught I know, but then I have no positive knowledge of the care or of the circumstances under which they were compiled; yet we have always been led to regard the Swedish and Prussian returns as very valuable.

In this state of matters I was not disposed to allow the point to remain unsettled for this country, and I recently undertook the somewhat onerous task of thoroughly searching the official returns, with a view of getting a figure that could be relied on. The determination which I am about to give can be erroneous only in the way of making the rate too low.

I found that there were registered in Edinburgh and Glasgow, in 1869 and 1870, about 52,000 births, and I found that within twenty-eight days after delivery at least 1 in 139 of the mothers had died. Now, several mothers additional may have died, and their deaths have been elsewhere registered, they having left their original residences. These would slightly increase the rate if they were found; but the rate is too low for another reason—namely, that all births of dead children are omitted. Now this very serious omission of a large proportion of the most dangerous labours leads to this rate of 1 in 139 being far too low. How very far too low, we may to some extent conceive when I call to mind that, among Collins' 16,414 women delivered, 164 died; and of these 164, nearly one-half had dead children! It may be said, then, as the result of this investigation—the most careful and complete, so far as I know—that at least 1 in 139 died; and I add, for the reasons above given, and for others, that I have no doubt that at least 1 in 120 died. These terrible results, gentlemen, or something closely approximating, we must accept meantime, however forcibly they may demonstrate that marriage and childbearing are a fearful ordeal for a young woman to encounter.

My estimate, gentlemen, of this lamentable mortality of lying-in women is 1 in 120 within four weeks; and it is useful to have a fixed period of four weeks for various reasons. But we must not allow ourselves to be misled into thinking that puerperal mortality is over in four weeks. You are well aware that many bad cases linger on beyond the month of four weeks, to die beyond the reach of these restricted statistics; and that many others owe their deaths to puerperality, although the occurrence is later than four weeks after the labour. I have already mentioned that I have most carefully prepared statistics showing a mortality of at least 1 in 107 within six weeks after delivery. Further, I have statistics analysed which do, I believe, show that the mortality of puerperal women does not again fall to its ordinary level till a period not of weeks, but of months, after delivery. It would be a grand work for our young statisticians to show the wave of special mortality, beginning with conception and ending some months after delivery. Statistics have already shown the great rise of mortality, or the great wave of it that passes over the sex during the childbearing age. But we want much more than this, and especially the wave for the average individual pregnancy, labour, and lying-in.

I must conclude this already too long discussion by saying that I believe that in this country nearly 1 in every 100 women delivered at or near the full time dies in parturition, or before the puerperal state and its effects have passed over. This is, no doubt, an awful statement for women and for men. Whether it will deter them from marriage or not when they come to know it I cannot say, for I have no analogy to guide me. The risk from railway accidents is comparatively a mere bagatelle, when taken in any point of view, and I have made no inquiry as to its influence in deterring from travel.

Even the fear that women may be deterred from marriage and childbearing must not deter us from unmasking the real extent of the dangers they encounter; but I must only spend a few words on puerperal morbidity. Besides dying at a rate of nearly 1 in 100, women have to encounter a vast amount of disease and suffering which does not end fatally. This has been called morbidity, in contradistinction to mortality. Miss Nightingale and Dr. Farr, besides having very favourable views of mothers' chances of survival and recovery, go a great deal further than this, and enunciate a doctrine to which it is difficult to believe they have ever given a moment's reflection. They regard ordinary women as having no need of long nursing after lying-in; for it is all over, say they, in a few days after retirement and delivery in the rude compartment of a hut. It is unnecessary to take up the time of any one of the most moderate experience in confinements and diseases of women among the poor or the rich, among the civilised or uncivilised, with a deliberate demonstration of the tragical injustice of their statement. I only refer to it here as it forms a contrast with the truth as to puerperal morbidity. This subject has been illustrated by many authors, among whom are Späth and Landau, who confine their researches to morbidity shortly after delivery. The latter, taking temperature as a criterion, estimates puerperal morbidity as affecting 1 in 6. His valuable experience was in an obstetric hospital, and it requires corroboration. Besides this, he takes no account of the many ulterior diseases coming on after so-called recovery.

Deaths during parturition or the puerperal state are often conveniently arranged in three sets:

1. Childbirth deaths.
2. Puerperal or metria deaths.
3. Accidental deaths.

A woman dying during post-partum hæmorrhage undergoes a childbirth death; a woman dying of puerperal fever undergoes a puerperal or metria death; a woman accidentally poisoned by laudanum shortly after delivery undergoes an accidental death. In cases such as these the placing of the death in its class is easy, but there is a large number of cases regarding which there may be just difference of opinion as to which of these three groups should receive them: hence the classification as used in practice cannot be relied on as embodying a scientifically accurate statement of any point—a circumstance which, for the conduct of various important discussions, is much to be regretted.

But though this is so, there is unanimity in placing puerperal fever deaths in the second category, that of puerperal or metria deaths, and in giving it the horrid pre-eminence over all other causes of mortality in the three combined categories. For obstetricians and for the world, then, this is the subject of first importance in midwifery, and it has attracted a corresponding amount of attention, and never more than at present, and certainly never with so much advantage.

The oldest writer on puerperal fever, Willis, whose book was published two hundred years ago, propounded a theory of this disease which is remarkably like that now in vogue among the best pathologists. He regarded it as having some connection with an uterine wound; but then he did not know the nature nor the anatomy of the uterine wound, and he did not think any of the other wounds or injuries of the lying-in woman important in

the matter. He regarded the disease as a fermentation in the blood, but his notions as to fermentation, its causes and results, were imperfect in themselves, and extremely unlike ours. He attributed to fancied sulphurous particles somewhat of the importance and place that are now given to the bacteria of Mayrhofer, of Lister, and of Heiberg, or to the micrococci or globular bacteria which Orth, and I believe Heiberg also, regard as holding the supremely baneful position among these noxious beings. Our new theories of puerperal fever must be tolerated because, as philosophers, we delight to frame them; and they have a certain utility which this is not the place to discuss. The new theories far surpass the old ones, which deserve more thorough displacement and rejection than the profession has yet awarded them. The new theories are based on an accumulation of facts whose collection is most creditable to modern science. These valuable facts have been the fruit of the ceasing to philosophise, and the struggling to observe and to experiment which are the characteristics of modern pathology. As in parturition, so in the puerperal state, the progress has arisen from discovering mechanism, although we do not speak of these advances in such terms. What are our discoveries in the anatomy of the lymphatics but the mechanism of puerperal fever, or a part of it? What are thrombosis and embolism? What is the conveying and diffusion of bacteria, or of any septic poison? What are our antiseptic precautions? By statistics, by observation, by experiment, we accumulate facts more or less pertinent to the subject, and we arrive at theories having a wider and more solid basis than those of our predecessors, who, long and till recent times, misled by the *ignis fatuus* of an essential puerperal fever, were destined to make little real progress till they threw that notion aside and began working at the matter again according to better method.

No theory of this subject can be regarded as final or sure. But the time has come when obstetricians should try to leave off the use of the convenient term puerperal fever, because it embodies error. There is nothing essentially puerperal known in it; nor is there anything of the nature of a fever, as that term is generally understood. A new name, already widely used, is to be found in the already comparatively old term, *pyæmia*. This new name can be of only temporary utility, but that utility will be very great, and continue till advancing science displaces it by a better, as it should now displace puerperal or childbed fever. It will then have served its time by carrying the ideas of generations of practitioners away from the old, flimsy, and extensively erroneous speculations of the past to the more substantial of this day. It is not to be supposed that *pyæmia* is a term to be analysed into its component parts and held as implying purulent blood. That was once the meaning of *pyæmia*, but it is not so now. The crude pathology of Piorry is already almost forgotten, and his term *pyæmia* is used extensively among the best pathologists as a comprehensive word, identical with or including the septicæmia and ichoræmia of certain others. It sounds like an adoption of humoralist views, but in it there is as much of solidism as of humoralism, and there is in it vastly more of modern science than in the term puerperal fever.

(To be continued.)

### AN UNIQUE CASE IN MIDWIFERY PRACTICE.

By J. WARING CURRAN, F.R.C.S.E., L.K. & Q.C.P.I.,  
Surgeon Mansfield Woodhouse Hospital, Medical Officer Mansfield  
Union, Medical Officer of Health, &c.

THE history of the following case appears to me as interesting as it is unusual:—

One night, about ten months ago, I was summoned to assist a midwife at an obstetric case, some distance from

my residence. Upon arrival I found the patient a *prima para*, aged about seventeen years, and on inquiry learned she had been in labour two days. A vaginal examination at once detected a hand low down, on the perinæum, in fact, with a coil of funis in front, and, strange to say, further examination discovered a foot presenting also. I determined at once to turn, but for the first time in my life, found I was utterly unable to do so, owing to the waters having been eliminated rendering the parts dry, and considerable traction having been made over a lengthened period by the midwife on the arm, as she mistook it for a footling. I summoned to my assistance another surgeon, who, unfortunately, in his efforts to turn, tore away a leg. The case assumed a most serious aspect, when we called in another medical gentleman, that we might perform embryotomy. The result of our combined exertions was that the limbs and body of the child were removed, but the head remained. Our efforts to extricate it were fruitless: the blunt hook was used, and every means that could suggest itself resorted to, but with failure attending; the head lay like a cannon-ball in the interior of the uterus—the patient was young, and the parts contracted. Worn out by our efforts, we arranged on consultation—viewing the case in its worst possible aspect, considering the amount of violence resorted to, the lengthened period the poor girl had suffered, and the fact of the head with a portion of the cervical vertebræ remaining *in utero*—to leave her for a couple of hours. Upon my arrival home, I found another obstetric case had to be attended to, which delayed for some time longer my return to our patient, whom I found in the course of five or six hours considerably restored and with more power in the pulse. On examination I found the head still lay in the uterus, which had contracted on it. I scarcely knew how to act; but I gave the woman a full dose of ergot with belladonna, and in the course of twenty minutes commenced friction over the uterus. I was rewarded by uterine pains, which became satisfactorily and regularly established. I repeated the belladonna, and after some trouble got my finger into the uterus and in the socket of one of the orbits, where I kept it until I extracted the head. The placenta came easily; the girl lay at death's door for a week: but the constant attendance she received at the hands of my professional colleagues, and with the aid of excellent nursing, the woman made a good recovery, and is again, I hear, *en route*. The case in its entirety reveals the difficulty at times obstetric cases present and assume, and the impossibility of following any stereotyped series of rules, as it demonstrates the prudence of waiting patiently, and not rushing at the performance of an operation that was our *dernier ressort*, and which upon a second consultation we should have been compelled to perform with a much less chance of saving our patient's life, however it might have added to our professional repute, for true it is no woman should die undelivered if there be any science in obstetric medicine.

P.S.—The combination may seem strange, but I am always in the habit of either administering belladonna with ergot, or of giving them in alternate doses (when necessary) to the parturient.

The University of Edinburgh.—Professor Spence, in addressing the candidates for degrees on capping-day (Saturday, August 1,) paid a warm tribute to the services of Dr. Hughes Bennett. "Gifted with great talent; as a teacher eloquent, enthusiastic, and energetic, and possessing the power of exciting enthusiasm in others, his great object seemed to be to instruct the students how to observe and to teach themselves. Eminent in his special department—great as a clinical teacher—his former pupils will regard him with gratitude for what he taught, and for the impulses he gave, whilst we, his colleagues, will miss him alike in the senate and in social life. His labours have added lustre to this University, and few names will more deservedly hold a place amongst its worthies than that of John Hughes Bennett." These remarks were received with much applause.

**CRIMINAL LUNATICS.**

---

FROM the Superintendent's Report of the Broadmoor Criminal Lunatic Asylum, which we have before us, we gather that the daily average number of criminal lunatics resident during the year in the asylum was 508. In 1872 the average number was 503, and in 1871 it was 483. Thus we may calculate on at least 500 such inmates as permanent.

All the inmates of Broadmoor are "criminal lunatics," and they are all, therefore, persons whose freedom has been forfeited by the commission of some offence, but who, instead of being retained in prisons, are sent there for the purpose of being treated in a manner suitable to their insane condition.

We are told that the opinions often expressed as to the value of out-door employment as a remedial agent in the treatment of insane persons have been abundantly confirmed in the working of this asylum, but the adoption of such employment in the open fields, and the resemblance which exists between this asylum and a county asylum in its general plan and construction, are necessarily attended with a certain amount of risk of the occurrence of instances of escape. In the management of this asylum the safe custody of the inmates is a matter which has, however, always been kept prominently in view, and the result may be seen by comparing the rate of instances of escape from this asylum with the rates which have obtained in other institutions.

The great bulk of "criminal lunatics" in England and Wales are now collected in Broadmoor, but there is still a sufficient number of criminal lunatics distributed in various county and other asylums to afford the basis for a comparison; and, although the number detained at Broadmoor has been constantly and steadily increasing, whilst the number in county and other asylums has been commensurately decreasing, the total number treated there during the last ten years does not differ very greatly from the total number treated in all other asylums in England and Wales combined, during a similar period.

A series of carefully compiled statistics show that during the ten years 1863-72 the aggregate of the yearly totals of criminal lunatics under care in the various county and

other asylums in England and Wales, with the exception of Broadmoor, was 5,937, and that the number of instances of escape was 43, giving a percentage of .74 instances of escape upon the aggregate of the yearly totals of numbers treated; and that the aggregate of the yearly totals of criminal lunatics under care in Broadmoor during the ten years and four months, from May 1863 to 29th September 1873, was 5,042, with five instances of escape, giving a percentage of .099, or less than one-seventh of the rate in the other asylums referred to. A calculation based upon a computation of the daily average number resident in the two cases shows a still greater difference, in consequence of the average period of detention of each inmate being longer in Broadmoor than in the other asylums. This does not imply that the greater rate of instances of escape from county asylums is due to any want of care. The primary function of a county asylum is the cure of its inmates, and this object is best attained by a concession of a considerable degree of freedom of action.

The death-rate is markedly less at Broadmoor than in the aggregate of other asylums, and it may be assumed that the bodily health of the inmates has been less infirm than that of the criminal lunatics detained elsewhere, and the much smaller percentage of instances of escape which have occurred may therefore be reasonably accounted for in part by the greater amount of supervision resulting from a larger staff of attendants, and in part by more restricted freedom.

If it be asked whether it is possible to lessen still further the risk of escape whilst preserving the benefits of field employment and exercise to those who most require and who are least inclined to abuse them, we must not forget that under the term "criminal lunatic" two very different classes of persons are comprised.

One class consists of those who, having been charged with the commission of some criminal act, have, either whilst awaiting trial, or when arraigned, or when tried, been found to be insane, and have in consequence been ordered to be detained during her Majesty's pleasure; and the other class consists in those who have been certified to be insane whilst undergoing penal servitude in convict prisons.

These two classes do not include all descriptions of criminal lunatics, but they form the bulk of those who are sent to Broadmoor. The former class consists mainly of persons whose offences have been the direct results of their insane state, and who, up to the time of the outbreak of their insanity, have in many cases led honest and industrious lives. The other class consists chiefly of habitual criminals, whose offences against law and order are part of their everyday life.

As to persons acquitted on the ground of insanity, or found insane before trial, the order of the court under which they are detained is that they shall be kept in strict custody until her Majesty's pleasure shall be known. In the other class a definite sentence of penal servitude has been inflicted.

Persons belonging to the latter class, who recover before the expiration of the term of their sentence, are liable in the ordinary course to be returned to a convict prison to complete the term, so that instead of having the bright prospect of the hope of release to promote recovery, that event becomes scarcely desired, inasmuch as it would be

attended with penal consequences ; and, lest the exercise of self-control and orderly behaviour might, when the more acute stage of insanity has passed, be interpreted as indicating recovery, interest as well as inclination appear to lead towards an opposite line of conduct, and thus disorderly habits are apt to become more strongly confirmed, and for the safe custody of such inmates arrangements similar to those of an ordinaty asylum do not suffice.

Those, however, who are confined during her Majesty's pleasure have no fear of penal servitude before them, should they recover ; on the contrary, when they begin to reflect, they soon perceive that instead of penal consequences being entailed by its being considered that they are again sane, their chief hope of ultimate liberation lies in such an opinion being justified by their good conduct and self-control.

The report states that all the men who effected their escape during the past year were under sentence of penal servitude, and the desire to avoid the possibility of returning to prison was doubtless largely operative as a motive for escaping.

Moreover, we are told that all who have at any time escaped since the opening of the asylum, and who have not been retaken, have been persons under sentences of penal servitude.

Of those under detention during her Majesty's pleasure, who have been at any time admitted since the opening of the asylum, all who have not died, or been legally discharged, are still inmates. Only two men belonging to this class have ever escaped, and both were recaptured within very short periods.

Many of those under detention during her Majesty's pleasure are persons of very violent propensities, who labour under dangerous delusions, and who therefore require very vigilant supervision, but for the efficient management of those who belong to the convict class it is necessary to be provided also with means for controlling criminal habits acquired before the onset of insanity.

The conclusion arrived at by the superintendent from these facts is, that arrangements suitable to one class are not suitable to the other, and that the complete separation of the two classes could not fail to be highly conducive to the efficiency and order of the asylum. We regret to learn that the construction of the asylum is such as to render it doubtful whether it would be possible to accomplish this object satisfactorily without providing entirely separate buildings for the convict class.

The existing buildings would probably afford suitable accommodation for the class detained during her Majesty's pleasure ; although to render the asylum a place of safe custody even for this class, some improvements in the boundary walls of the courts and of the kitchen garden, and some increase in the extent of enclosed ground, are recommended. The infrequency of escape of persons belonging to this class indicates that there is no necessity for greatly restricting the amount of field employment and exercise which have hitherto been accorded with so much advantage in a remedial point of view.

The points to which we have referred are clearly set forth in the report, which is also full of other interesting facts, all of which are ably marshalled in this report for the Council of Supervision.

## THE RELATIONS OF THE PROFESSION TOWARDS HOMŒOPATHS.

FROM a Presidential Address to some Homœopathic Congress, which occupies the leading position in a recent homœopathic periodical, we cull the following statement, which we suppose represents the story upon the faith of which homœopaths maintain their character as martyrs. The lecturer asks :—

“What does this exclusion and professional excommunication of homœopathists mean ? It means that a majority of the profession allege that some of their colleagues who possess the same qualifications as themselves, who have been educated at the same schools and walked the same hospitals, are unworthy to be regarded as members of an honourable profession—are, in short, immoral individuals, with whom it would be ignominy to associate. And why ? Because this excommunicated minority, taught by careful experiment, are convinced that many diseases are best treated by medicines which direct experiment shows are capable of acting on the same parts as are affected by the disease—a rule of practice which the majority only acknowledge in the case of a few diseases, as they have no experience either for or against the validity of the rule beyond these few diseases. The most exalted virtue could scarcely contend that there was aught of immorality in the belief that a great many—instead of only a few—diseases are best treated by medicines that act similarly to the morbid cause ; and yet it is for so believing that we are treated by our colleagues in a so-called liberal profession as though we were guilty of some unpardonable moral delinquency.”

We are obliged to characterise this statement as a gross misrepresentation, indefensible in any speaker who was presumed to be acquainted with the utterances of professional journals on the subject. The medical profession does not refuse to associate with homœopaths for any such reason. but, on the contrary, regards with the most perfect toleration the theory and practice of *similia similibus*. They regard it as unscientific and illusory, but they do not take upon themselves to say that its practice is the result of anything else than a delusion. But they cannot say as much for the practice of infinitesimalism, which, the occasion obliges us to state plainly, they regard as a false pretence, the employment of which disentitles any person to associate with them.

Medical men can imagine that homœopaths may honestly believe in the *similia similibus* theory, but they cannot be expected to conceive that the majority of the fraternity honestly believe in billionths, and they are therefore obliged to conclude either that homœopaths treat disease by effectual therapeutics under the pretence of giving infinitesimals, or that they pretend to treat disease by infinitesimals, well knowing that they are not treating it at all. This is the reason for the exclusion of homœopaths by the profession. It is for the public to say whether an injustice is thereby done to them.

## Notes on Current Topics.

### Practical Physiology.

WE are pleased to find by a paper from the pen of Dr. C. Watson on “Practical Physiology,” in the last number of the *Glasgow Medical Journal*, that the system of teaching histology first proposed by Professor Bennett (who first

taught practical histology in this country), now universally adopted in our metropolitan medical schools, is gradually making its way into *all* the Scotch universities.

It is obvious that such a course is now almost indispensable for a right conception of perhaps the most difficult part of the medical curriculum. It is therefore much to be regretted that such practical courses are not compulsory in Scotland. The number of students attending Dr. Watson's class undeniably shows the general feeling amongst students of the want of opportunities to extend their practical knowledge rather, than to trust to the mere exercise of memory.

Dr. Watson's third course has been conducted on the principles advocated by Professor Rutherford, of King's College, in the *Quarterly Journal of Microscopical Science* for January, 1872, and we doubt if a better could have been adopted. The programme shows that much time and great care has been bestowed on the study of the simple tissues and elements. Nevertheless, the course would have been much more valuable had the histology of organs and compound tissues formed a part.

Carminic acid was generally used to stain the tissues for examination. We would suggest the adoption of hæmatoxylin staining fluid, which possesses many advantages over carmine, not the least being the simplicity of its preparation, its great selective property, the short time acquired for its action on the tissues, and lastly, its inexpensiveness.

### Monobromide of Camphor, $C^{10}H^{15}OBr$ .

DR. BOURNVILLE, of the Paris School of Medicine, strongly advocates the therapeutical employment of this compound in cases of delirium tremens, epilepsy, hysteria, infantile convulsions (due to the irritation of teething), chorea, paralysis agitans, &c. He gives the results of numerous interesting experiments, and also the histories of various cases treated successfully. In hydrophobia, tetanus, and epilepsy, he recommends a solution of the monobromide in alcohol and glycerine to be injected under the skin.

### Social Science Congress.

At the recent meeting of the Social Science Congress the following questions for discussion were selected by the Committee of the Public Health Department :—

1. What are the best methods of sewerage towns and disposing of their organic refuse?
2. In what way can healthy working men's dwellings be erected in lieu of those removed for the purpose of carrying out sanitary or municipal improvements for other purposes?
3. What influence has the employment of mothers in manufactures on infant mortality, and ought any, and what restrictions, to be placed on such employment?

### The Registrar-General's Quarterly Report.

FROM the Registrar-General's Quarterly Report it appears that in the United Kingdom 288,476 births were registered during the three months of April, May, and June, 1874, whilst the total number of deaths registered

during the same period was 167,744, showing the natural increase of population to be 120,732.

The number of marriages during the quarter ending the 31st March, 1874, was 115,348.

Thus, the birth-rate in the United Kingdom in the second quarter of 1874 was 35.7 per 1000, and the death-rate 20.8. The marriage rate in the first quarter was 14.4 per 1000.

The resident population of the United Kingdom in the middle of 1874 is estimated as follows :—

England and Wales	...	...	23,648,609
Scotland	...	...	3,462,916
Ireland	...	...	5,300,485
Total	...	...	32,412,010

### Diapedesis.

A GOOD practical paper, by Mr. J. Needham, of the London Hospital, "On Diapedesis, or the Passage of Blood-corpuscles through the Walls of the Blood-vessels, and How to Observe It," appears in the present number of the *Monthly Microscopical Journal*.

After dwelling on the importance of the subject, a very lucid description is given of the various methods employed for its demonstration. For this purpose he especially recommends the mesentery of the toad and the tail of the tadpole of the frog, or toad; directions are also given for observing it in the mesentery of the guinea-pig, wing of bat, tail of fish, and tongue and foot of frog.

The following method appears so very simple that anyone possessing a microscope with a  $\frac{1}{4}$  in. objective can prove for himself the long disputed fact: "The tail of the tadpole can be arranged with great facility, and affords a very interesting object. The animal is rendered motionless by placing it in a  $\frac{1}{4}$  per cent. solution of curare. It is then placed on an ordinary glass slip, the tail covered with a piece of thin glass, and kept moist by the addition at intervals of a little water."

The second part of the paper is occupied by a minute description of the process; and further on, in the third part, he warns the observer of a number of fallacies that are likely to occur, and gives the various theories held by different observers of the escape of the corpuscles through the unruptured vessels.

The fourth and last part deals with the origin of pus. Whilst admitting its origin to be principally from the amoeboid blood corpuscles, he nevertheless believes that the observations of Steiner and Recklinghausen go directly to prove origin, in part at least, by proliferation of connective tissue corpuscles.

The above brief outline of the paper can convey but a limited idea of the manner in which the subject is treated. We should therefore advise all interested in the subject to procure the paper and study it for themselves.

### Locomotion for Irish Dispensary Doctors.

IN a letter recently addressed by Dr. Kisby, of Lahardane, in the county Mayo, in defending himself against a charge of having omitted to attend a fever case more than five times, he says :—

"I can solemnly declare I was handed the ticket on

Sunday morning, 28th of June, and went without delay. I attended again on 30th June, again on 2nd July, again on 4th July, and again on 7th July, as my Medical Register shall testify; and further, I can show no less than 7 visiting tickets—all of which were in different directions—some very far distant, one of which was to a fresh case of fever. On the other side I give details. On 28th June, I attended Mary Murphy, Derrybick, *which took me over eight hours*. On same day I attended Ellen Fleming, Cloghbrack, and also at Massbrook on 9th July. Ticket to Laragon *took me nine hours to arrive home*. On same day I went to Acalutseen, another direction. Then on 10th July a *new fever case*, which I saw again on 12th; also on 10th I visited at Massbrook mountain, different directions, on another ticket. On 11th to Castlebar with registration returns. On 12th another ticket to Ballyduffy. I think, gentlemen, no fault can rest with me."

This poor gentleman is one of those unhappy medical officers who suffer under the scandalous abuse of the unlimited authority which the law unfortunately confides to guardians and dispensary committee-men. He plainly alleges in his letters to the guardians and the Local Government Board (with what truth we do not take upon ourselves to say) that this persecution is carried on by the brother-in-law of the relieving officer, who is, most improperly as we think, acting as a guardian, because the medical officer has had occasion to report the relieving officer for gross neglect of his sanitary duty.

We do not enter upon the controversy as to the right and wrong of either party, but we reiterate that, supposing Dr. Kisby to be the worst public officer in all Ireland, the system which allows of abuses so gross as those which his letter illustrates urgently requires amendment.

It is a fact that any ill-disposed or unprincipled guardian (of whom most boards and committees possess one or two) could with complete immunity pursue a similar course with the most conscientious and industrious public officer, and thus compel him to resign his appointment.

### Effect of Enlarged Thymus.

In an interesting pamphlet entitled "Observations on a Peculiar and Dangerous Affection of the Respiratory Organs commonly met with in Infants and Children," published by Dr. Finch, of Colchester, we find a record of five interesting cases of disease which the author believes to depend on enlargement of the thymus. In order to give Dr. Finch's views, we will quote one of the cases, selecting the only one of the five in which the autopsy was made. This is it:—

On July 31st I was sent for to see another child of the same family, also a boy, aged three years, of stronger build and not so delicate in appearance as his brother. I had been attending him at intervals for nearly two years, for hoarseness and roughness of breath, with at times great difficulty in respiration. Eighteen months back, at the beginning of 1872, when recovering from scarlet fever, I had seen him in his first attack, when for eight or nine days his breathing was most painful and oppressed; since then he had never breathed quietly, always making some noise; when from any trivial cause he was out of sorts this increased to almost a continual roar. Hitherto perfect quiet in the atmosphere of a warm room, liquid food, and infinitesimal powders of hyd. c. creta had sufficed to bring him round.

When I saw him at the present time his breathing was rather faster than it should be. In expiration the air made a loud rustling sound, inspiration was not so noisy, and had a whistling character; his face was rather anxious and pale, nothing could be seen amiss in the interior of the throat or

mouth, one tonsil was prominent, the other not visible, on both sides of the neck and beneath the chin could be felt glands, the jugular veins were turgid with blood, the sternum projected in its upper part, and the cartilages of first two or three ribs curved inwards, the tongue was clean, and bowels rather costive. The pulse was between 80 and 85, all chest sounds were smothered by the noise of his breathing. He said he did not feel ill, and his father told me that he seemed all right, excepting his loud breathing. I treated him as on former occasions, and when I saw him next evening he was much improved. He continued to mend until August 4th, when he was so much better, that I allowed his going out of the room and returning to ordinary diet. The rough breathing was still audible, like air being forced through a small orifice. In addition to the powders night and morning, he took small doses of iodide of potassium.

The next day I did not see him. I was told he was well enough to walk out with his sister, but objected to the passers by looking at him, in wonder where the noise he made in breathing came from.

Next day, Aug. 7th, he was worse, the difficulty in breathing had increased, he was kept in bed, and because of his restlessness clothes were put upon him, he gasped for breath like one in an asthmatic attack, he was easiest in the prone position with a pillow under the chin. In the evening he was much worse, the difficulty in breathing was intense, merely a narrow stream of air entered the lungs, the face was pinched, the eyes stared, the nostrils worked to and fro with every breath, the lips and nails were blue, and extremities cold, he was perfectly conscious. Mr. Nunn saw him in consultation with me about seven o'clock, p.m. A blister was ordered to be placed across lower part of throat, with chlorate of potash mixture every two hours. I saw him again at 12 o'clock, midnight. The blister could not be kept *in situ*, an emetic produced but slight relief, every few minutes he dozed off, and awoke to fight for breath; gradually he became quieter, though still conscious, and died the next morning between six and seven o'clock, worn out.

Aug. 10th.—Three days later I assisted Mr. Nunn at the examination of the body.

The body was thin for a child; the skin was discoloured and livid in places, particularly on the throat and back. It was well formed with one exception; the sternum was prominent.

On opening the chest, the upper portion of anterior mediastinal space, behind the bone of the sternum, was seen to be occupied by a dark pink mass, extending upwards to near the lower border of cricoid cartilage, and downwards to a level with the second intercostal space, it adhered to under surface of sternum, and was dissected away with difficulty. We agreed it was an enlarged thymus body, its surface was smooth, of uniform pale red colour, and presented a few indentations. It was about half as broad as the palm of my hand, and twice that in length; it was thickest where it had lain just above the sternum, from thence, both upwards and downwards, it got thinner and narrower; on cutting into it a quantity of pinkish fluid escaped, and it became manifestly less in size. It seemed composed for the most part of cells about the size of a hazel-nut, and one or two a little larger. The parenchyma was firm, and as far as we could judge healthy. The heart and large arteries were perfectly sound. The lungs were full of blood, but otherwise in good condition. The lining membrane of both larynx and trachea was injected and darker than natural, and adhering to the lower half was much tough dry mucus.

I had no means of weighing the gland, a piece of sheep's lung cut as near as I could recollect to the size weighed two and a half ounces; from this, allowing for the difference of consistency and the presence of cells and fluid, I concluded the thymus body was something below two ounces in weight.

Dr. Finch believes that paralysis of the dilators of the glottis, from the pressure of the enlarged and distended thymus body impeding the function of the recurrent nerve on one or both sides, is the probable cause of the most important symptoms in this and his other cases. That section or irritation of the inferior laryngeal nerves produces suffocative dyspnoea the numerous experiments of Legallois testify; and Dr. John Reid, in his pathological researches demonstrates that severe dyspnoea, amounting to suffocation, follows irritation or compres-

sion of the inferior laryngeal nerves. There are also numerous cases on record in which an aneurismal sac has caused suffocation by pressure on these nerves.

Sir B. Brodie relates the case of a girl aged seven years troubled with frequent attacks of difficulty of breathing, and who died in one, in whom after death the thymus, enormously enlarged and distended with fluid, was the only lesion present sufficient to account for the symptoms. Dr. Ley, in his monograph on laryngismus stridulus, fully describes and demonstrates the effect of continued pressure on the recurrent nerves.

It has been ascertained that the pressure exerted by an enlarged thymus is capable of flattening the tracheal tube and of causing an approximation of its sides. Dr. Finch thinks this alone, and in the absence of other morbid processes, from the peculiar structure of the trachea, could very rarely seriously impede the respiratory process, but he admits that in extreme cases, when the function of the dilators of the glottis is already interfered with, and the action of the heart weakened, the lungs become slowly engorged, and mucus having had time to accumulate in the bronchi, a slight additional source of exhaustion might easily and suddenly prove fatal.

The sudden and complete arrest of the breathing observed in laryngismus stridulus implies spasmodic action of the laryngeal nerves and muscles, but in Dr. Finch's cases spasmodic action was not present from first to last. To the accumulation of mucus in the larger bronchial tubes, slowly though constantly increasing, the most frequent cause of death, after delayed tracheotomy, combined with the urgent dyspnoea previously existing, and consequent prostration of strength, he attributes the fatal result.

In Dr. Finch's cases the dyspnoea was permanent, the remissions incomplete, and though the difficulty in breathing did not at all times present the same urgency, it was always present. There was long-continued hoarseness possibly from compression or lesion of the superior laryngeal nerve.

This nerve, says the author, besides supplying the laryngeal mucous membrane, also supplies the crico-thyroid muscles; it is the office of these muscles to depress the thyroid cartilage; this depression of the thyroid increases the distance between the points of attachment of the vocal cords, their tightening follows, and the air passing over them causes them to vibrate, and the higher notes of the voice to be produced. If, then, the crico-thyroid muscles do not act, the vocal cords cannot be made tense and the higher notes of the voice are not uttered—it is hoarse, deep, and rough.

This loss of part of the vocal sounds is not uncommon at all ages, and is very frequently met with in children who have enlarged cervical glands, from whatever cause arising.

Dr. Finch remarks that in most cases in which the thymus has been found enlarged, a portion of the enlargement has been owing to the presence of an unnatural quantity of the secretion peculiar to it, and it seems possible that this might gather very quickly from congestion and other causes, and thus afford some explanation of the frequently almost sudden commencement of the difficult breathing. Generally this comes on dur-

ing sleep, and the position of the body and head would have some influence.

### Appropriation of Celebrated Names by Quacks.

AN Act of Parliament has just been printed to render "personation" a felony, and no doubt resulted from the trial of the Tichborne Claimant. It is now enacted that if any person shall falsely and deceitfully personate any person, or the heir, executor, or administrator, wife, widow, next of kin, or relation of any person, with intent fraudulently to obtain any land, estate, chattel, money, valuable security, or property, he shall be guilty of felony, and liable to penal servitude for life, or to not less than five years, or to imprisonment not exceeding two years with or without hard labour, and with or without solitary confinement. It is not our function to say whether the obtaining of money under false pretences which is practised by many of the obscene quacks by making use of the name and credit of celebrated physicians will come within the terms of the clause quoted above. If so, we may perhaps hope to observe a speedy disappearance of the rascals who have been pursuing their calling under the names of Brodie—Ricord—Watson—and other men high in public popularity. It ought to be recognised by the law that "he who filches a good name" steals that which is as hard-earned and valuable a property as any trade mark.

### A Simple Method of Reducing the Dislocation of the Forearm Backwards.

DR. ALEXANDER MURRAY writes to the *New York Medical Record* that he has reduced five cases of the above-mentioned dislocation by the method to be described.

Supposing the dislocated arm to be the left. Dr. Murray takes his position at the outside of the dislocated arm, and places the palm of his right hand to the palm of the patient's left, dove-tailing his fingers between each of the patient's. In this way, a firm hold is secured for extension. He then places his elbow as a fulcrum and for counter-extension on the forearm in front and against the lower end of the humerus, and by a steady pressure downwards and backwards, and at the same time flexing the forearm towards the shoulder, in a few minutes the luxated bones slip into their natural places. Other dislocations of the elbow can be reduced by the same method.

### A Reward for Services to Science.

THE *Wiener Medizinische Presse* says that M. Fourton, the Minister of Education of Paris, has introduced a Bill into the National Assembly, the object of which is to reward the services of the naturalist Pasteur, Fellow of the Academy of Sciences and Professor in the Paris Faculty, by an annuity of 1,200 francs. In support of the Bill it was stated that M. Pasteur had clearly proven that the old axiom that "Life alone produces life," applies to all objects, even those microscopically minute. It was also stated that his researches on silk-worm culture, on wine, vinegar and beer, commanded the highest approbation.

**The Internal Administration of Phosphorus.**

THE difficulty of finding an appropriate vehicle for phosphorus in its medicinal uses has long been recognised. Balsam of tolu has lately been suggested for this purpose. Experiment has shown that four grains of phosphorus are perfectly dissolved by ninety-six grains of washed tolu, if melted together under water and well stirred.

The preparation so made, says the *Philadelphia Reporter*, when examined microscopically, does not show any particles of undissolved phosphorus, and when seen in the dark, and rubbed between the fingers, it gives off a perfectly equally distributed light.

This preparation may, therefore, be formed into pills, with every confidence in the equal distribution and activity of the phosphorus.

**Anæsthetization during Sleep.**

DR. CLUNESS reports in the *Pacific Medical Journal* two cases of successful chloroformization during sleep.

The first case was that of a little girl, aged eight years, in whom, as a sequel to acute otitis media, the mastoid cells of one side became inflamed. Chloroform was administered upon a four-by-six piece of surgeon's lint, held as near the child's mouth as possible during sleep without coming in actual contact. Not the slightest effort was made by the child to avoid the inhalation of the anæsthetic, and in a few moments she was well under its influence.

The second case was on the person of a little girl two and a half years old, for the purpose of having a supernumerary toe removed from each of its feet.

**Persistence of Life after Apparent Death.**

SOME experiments as to how long after cessation of the phenomena of life attempts to revive may be successfully made, have lately been described by M. Böhn in the *Centralblatt*. They were made on cats, after injection of potassium salt into the blood. It was ascertained that after forty minutes' continuation of a state which could in no way be distinguished from death, life may be perfectly restored. Another observation was, that artificial breathing through an opening in the windpipe was not sufficient for restoration; the thorax must also be compressed at the region of the heart. Whether it is the mechanical stimulation thus imparted to the heart, or the slight variations of pressure produced in the arterial system, that is the essential point, is uncertain; but the compression was certainly as essential as the renewal of the air.

**Cholera in Vienna.**

SOME of the Vienna papers state that cases of cholera have recently occurred in that city. The *Wiener Medizinische Wochenschrift*, however, considers that this is an error, arising from the confusion with cholera of the cases of diarrhoea and vomiting occurring in children during hot weather. Since December there has been no case of Asiatic cholera in Vienna, and no instance of its occurrence reported from any of the provinces of the empire.

**British Association for the Advancement of Science.**

THE forty-fourth annual meeting of this Association commences at Belfast this day (Wednesday), and will last for seven or eight days. In Mathematical and Physical Science Professor Jellett will preside; in Chemical Science, Professor A. Crum Browne; in Geology, Professor Hull; and in Biology, Professor Redfern.

THE meeting of the Italian Medical Association will be held this year in Bologna, commencing on September 22nd.

THE Rev. John George Brighton, M.D., has been presented to the vicarage of Dormston, Worcestershire.

MAJOR BATHURST has erected a cottage infirmary at Cirencester, as a memorial to his late wife, and presented it to the town.

THE price of quicksilver has again advanced, and now stands at the enormous figure of £22 per bottle, with fair prospect of still higher quotations.

THE Council of the German Apotheker-Verein extends to British pharmacutists a cordial invitation to attend their session at Munich next month.

THE library of the Royal Medical and Chirurgical Society was closed on Monday, August 10th. It will be reopened on Thursday, September 10th next.

THE magistrates of Buda-Pesth have decided on erecting mortuaries in the churchyards of the city. It will be obligatory on all families inhabiting single apartments to bring the bodies of persons who may die in their rooms to it.

DR. WESTPHAL, who for some time held the office of Director of the Department for Diseases of the Mind and Nervous System in the Charité Hospital, has been appointed ordinary Professor of Psychological Medicine in the University of Berlin.

AT a special meeting of the governors, August 6th, S. Spratly, M.D., was elected surgeon to the Birkenhead Borough Hospital, *vice* H. O. Wilson, Esq., resigned through ill health.

ANOTHER accident on the Alps is reported. Early on Tuesday evening Mr. William Dury, of Youghal, left the hotel at Monte Rosa, and, not returning as soon as was expected, search was made for him. His body was found at the foot of the mountain, in exactly the same spot where Mr. Townsend lost his life two years since.

THE European Congress of Pharmacutists at St. Petersburg was to commence on the 13th inst., and continue until Tuesday. A number of excursions have been organised, and *réunions* for the evenings. The most important question for discussion is the formation of an International Pharmacopœia. The *Chemist and Druggist* announces its intention to publish a report of what may be of interest at this Congress.

THE ceremony of laying the foundation-stone of the New Asylum for the Central London Sick Asylum District, on the site of the Old Strand Union in Cleveland Street, was performed on August 6th by Sir Sydney H. Waterlow, the Chairman of the Central London Sick Asylum District Board.

THE first article in the *American Journal of Obstetrics* for May is by Mary Putnam Jacoby, M.D., being a paper read before the New York County Medical Society on the "Pathogeny of Infantile Paralysis." It occupies forty-four pages, and is pronounced by the *Pacific Medical Journal* to be a thorough and masterly production, reflecting great credit on the scientific acquirements and logical ability of its author. Such labours will tend much more to overcome the hostility to female doctors, than their pertinacious efforts to remove all distinctions of sex in medical education.

AT the Birkenhead Police Court an application was made by the police authorities for an order for the destruction of about 20 tons of American meat which had been seized at the Pacific Company's shed, Morpeth Dock. On Thursday afternoon an inspector visited the sheds, and found there about 250 casks of what purported to be salted meat and tongues, which had been discharged from a steamer. With the assistance of some of the company's men the casks were opened, and about 180 of them, amounting at least to 20 tons of meat and tongues, were found to contain nothing but rotten meat unfit for food either for man or beast. The stench was dreadful, and several of the workmen were ill from the effects of it, and it could be perceived at a distance of 300 yards. The meat was consigned to Messrs. Fair and Co., of Manchester.

BRANDRETH of the Pills has been obliged to make sundry interesting confessions under cross-examination in the Liverpool County Court. It seems he is also owner of the Alcock's Porous Plasters, without which the ailments of old women now-a-days are well-nigh incurable; and he swore that he expended between £1,500 and £2,000 a year in advertising them. Counsel, cross-examining the defendant, asked him whether his manager wrote the different testimonials which professed to come from various parts of the country. The defendant said he did not; whereupon counsel, looking at a sheet of printed testimonials, asked if one signed by John Smith was not written by the manager. The defendant replied that it was a genuine testimonial, and that he had the original, but the manager did not wish his name to appear, and the name of Smith was substituted. It was also stated that these pills are made in enormous quantity at Sing-Sing in America.

THE phenomena of digestion in insects is the subject of an interesting memoir recently communicated to the Belgian Academy by M. Felix Plateau. In a great number of cases (carnivorous insects, Orthoptera), the oesophagus dilates into a crop, terminating in a narrow valvular apparatus just before the intestine. The food, finely divided the mouth, goes into the crop, where it undergoes a

digestive action, aided by certain liquids, neutral and alkaline, and in carnivorous insects, in transformation of the albumenoid matters into something like peptone; in insects that feed on plants, in an abundant production of sugar from fecula. The valvular apparatus, into which the crop then forces the food, is not a triturating organ (its use is not stated). In many insects both it and the crop are wanting, and the food, going directly into the middle intestine, is submitted to a liquid secreted by local glands, which has various chemical effects, according to the species of insect. The author finds also "Malpighian" tubes (for secretion of urine and like matter), in the form of long sacks, or cæcums, connected with the alimentary canal.

WE are obliged to confess that we are heartily ashamed of the figure which our profession cuts in the witness-box, and we earnestly desire that medical men who are called as "swearers" in courts of law would exercise the mental discipline necessary to give an unprejudiced opinion without regard to the interest of those who call them in. We are far from suggesting that the varying opinions given are not honest (although many of the public will undoubtedly hold that view), but we are forced into the conclusion that medical men, when called upon to view a case, may and do view it through spectacles of the colour which their clients desire, and permit a foregone conclusion to interfere with the scientific truth of their evidence. When we see—as we have seen last week—physicians of such high reputation as Mr. Le Gros Clarke and Mr. Savory confronted with Dr. Ramskill and Mr. Hancock, and swearing to an opinion diametrically opposite to these gentlemen, we are not surprised that the public should say that medical opinions can be made to order, or else that medical science is groping in the dark. We do not see why, if a committee of competent physicians had adjudged upon the matter after careful investigation, they need have experienced any difficulty in arriving at the truth. It is obvious that medical evidence is of little use if it only muddles the comprehension of jurors, as it usually does.

A MEETING of public analysts took place last week, and was well attended, Dr. Redwood in the chair. The resolutions passed, when briefly epitomised, amount to the following:—The analysts will take into consideration the report of the Adulteration Committee, and will suggest amendments with a view to the legislation which will take place on the question next session. They object to the proposed reference of disputed cases to the officials of the Somerset House Laboratory in a manner which leaves no doubt of their opinion of that suggestion. The analysts present objected to a compulsory examination at South Kensington or elsewhere; but they suggested that public analysts to be hereafter appointed, if not analysts at the time, and incapable of producing proof of their competency for the post, should be called upon to produce proof of having studied for some time under a competent analyst. The report of the Adulteration Committee was condemned as defective, because it does not state what does and what does not constitute adulteration; and also because it contains a recommendation that, in the case of "mixtures," a

label announcing that fact should be deemed sufficient to the analysts, considering that the percentage of the ingredients should be stated. If faced tea is to be allowed, as recommended by the Committee, the analysts think that the Act ought to specify a distinct limit to the percentage of "facing," and not leave it to them to determine what is "fairly-faced green tea." Several minor resolutions were also agreed to, and the preliminaries of an analysts' association agreed upon.

#### On Subcutaneous Injection of Chloral in Asthma.

By Surg.-Major N. B. BAILLIE, Civil Surgeon, Bhaugulpore.

It does not seem to have occurred to any one hitherto to employ chloral by subcutaneous injection for the relief of spasmodic asthma, and I am therefore desirous of drawing attention to its value when used in that manner for the relief of this distressing affection.

It has been thus employed recently by Sub-Assistant Surgeon Banerjee, as an improvement on a suggestion of my own to him to use the drug in the ordinary mode: the immediate relief afforded is so striking, that I have no doubt when its use in this form is better known it will be eagerly sought for by those who are liable to attacks of the disease.

The following is a case of this sort in which the effect was very strikingly manifested:—

A scantily-clothed woman was carried into the dispensary one cold morning and deposited on the floor, her painful efforts to breathe absorbing all her attention, and rendering her quite unable to give any account of herself; from her friends it was learnt that she had been suffering for some weeks past from more or less difficult breathing which had culminated in the present most severe attack some twenty hours previously. Solution of chloral containing three grains in twenty minims of water, was at once injected subcutaneously at the back of the neck with so much advantage that, ten minutes later, the spasm had entirely ceased, and easy natural respiration had taken its place; the woman expressed her sense of the relief afforded her, and half an hour afterwards walked off to her house with her friends; she was seen again a few days later, having remained quite free from the affection, and as she has not been heard of since, it is probable that the attack has not recurred.

Several other cases of less severity than this have been also treated with equal benefit.

Two other affections occur to me in which it may prove useful, tetanus and puerperal convulsions, in both of which it has been administered with advantage by the mouth, and should an opportunity offer I shall certainly make a trial of it in hydrophobia.—*Indian Medical Gazette.*

#### THE BRITISH MEDICAL ASSOCIATION.

THE forty-second annual meeting of this Association, held at Norwich during the past week, was unfortunately the reverse of a success; why this should be we are unable to divine. The papers announced to be read were quite up to the average in point of interest, whilst the rendezvous chosen has great historic and antiquarian attractions. The surgical instrument department was also more than usually well represented, most of the principal makers sending large stocks, with several novelties, supplemented with a magnificent display of microscopes by Messrs. Pillischer, Collins, &c., the former introducing for the first time in England some valuable pathological specimens, which were the admiration of all beholders. Amongst those we examined were specimens of carcinoma of liver, pneumonia and emphysema of the lung, diseased kidney (Bright's), cirrhosis of liver, bronchitis chronica, human spinal cord, &c. All, however, proved futile to attract visitors, and when, on Wednesday morning, the register of members was issued, less than 190 had put in an appearance. Readers of papers grumbled at having to hold forth to comparatively empty benches, and exhibitors appeared chagrined at being unable to do business.

Tuesday's proceedings were chiefly of a preliminary character; the Committee of Council and of State Medicine met. Several members of the Association attended the Cathedral service and listened to a discourse by the Rev. Canon Heaviside. A general meeting was afterwards held, when the President, Sir Wm. Fergusson, resigned his position, and Dr. Copeman, of Norwich, was installed in the vacant chair, and delivered an address. A vote of thanks to the ex-President was passed, the Report of Council read and adopted, and the re-election of Mr. Fowke, the general secretary, concluded the day's programme.

In Wednesday's proceedings a little more interest appeared to be taken, and some of the papers attracted a fair sprinkling of hearers. The following were set down for the several sections:—

#### MEDICINE.

- RANSOME, ARTHUR, M.D. Some Observations on the Mechanism of Cough.  
 FOTHERGILL, J. MILNER, M.D. The Systemic Indications of Chronic Bright's Disease.  
 MAGNAN, Dr. (Paris), and MIERZIEWSKI, Dr. (St. Petersburg). On the Anatomical Lesions in General Paralysis, illustrated by Microscopic Preparations.  
 ROSS, JAMES, M.D. On the Action of Mercury.  
 RINGER, SIDNEY, M.D. On the Action of Croton-Chloral in Certain Forms of Megrim.  
 THOMPSON, JAMES, M.B. Leamington Spa; Climate; and Mineral Springs.  
 PETER, Dr. (Paris). 1. Accidents that may happen to Pregnant Women Suffering from Disease of the Heart. 2. Effect of Tobacco-Poison on the Vagus Nerve. 3. On the Plessigraph.  
 PRANGLEY, T., Esq. (Aylsham). On Diphtheria.  
 BRADBURY, J. B., M.D. Notes on Six Cases of Hydatid of Liver treated by Puncture.

#### SURGERY.

- BAKER, J. WRIGHT, Esq. Case of Lithotomy; the Nucleus of the Stone being a broken piece of Elastic Catheter.  
 CORMACK, SIR JOHN ROSE, M.D. Successful Resection of the Shoulder Joint in Case of Gun-shot Wound.  
 BARWELL, RICHARD, Esq. A New Method of Treating Chronic Synovitis, more especially of the Knee.  
 DRYSDALE, C. R., M.D. When, and for how long, should Mercury be used in the Treatment of Syphilis?  
 CORMACK, SIR JOHN ROSE, M.D. Recovery from Apparent Death induced by the Inhalation of Chloroform: a Case described principally with a view to show the Therapeutic Value of Inversion of the Body when there is Syncope from General Anæmia.  
 SIMS, J. MARION, M.D. 1. Nélaton's Method of Resuscitation from Chloroform Narcosis. 2. On the Management of the Pedicle in Ovariectomy.  
 CLOVER, J. J., Esq. New Apparatus for Administering Ether, &c., with or without Nitrous Oxide.  
 DE MERIC, VICTOR, Esq. Hereditary Syphilis in the Adult.

#### OBSTETRIC MEDICINE.

- DUNCAN, J. MATTHEWS, M.D. Laboratory Note: on the Tensile Strength of the Fœtus.  
 TAIT, LAWSON, Esq. Operations for Fibroma of the Uterus.  
 STEELE, A. B., L.K.Q.C.P. On the Treatment of Mechanical Dysmenorrhœa and Chronic Induration of the Cervix Uteri.  
 DRYSDALE, CHARLES R., M.D. On Dysmenorrhœa.  
 WRIGHT, FREDERICK W., M.D. On Decoliation as a Mode of Delivery in Arm-Presentations.  
 HICKS, J. BRAXTON, M.D., F.R.S. On the Adaptation of the Galvanic Cautey in Gynæcology.

#### PUBLIC MEDICINE.

- SMART, W. R. E., M.D., C.B., Inspector-General of Hospitals and Fleets. On the Relative Frequency, the Causes and Modes of Suicidal Attempts in the Navy and Army.  
 RUMSEY, H. W., M.D., F.R.S. The Correlation of Sick Poor Relief and Public Health Administration.  
 BEVERLEY, MICHAEL, M.D. (Norwich). Hospital Hygiene, illustrated by Reference to the Norfolk and Norwich Hospital, in the Past, Present, and Future.

FOX, CORNELIUS B., M.D. Water Analysis; as it should, and as it should not be performed by the Medical Officer of Health.

MACINTOSH, ANGUS, M.D. 1. The Cause, Mode of Propagation, and Non-Contagious Nature of Enteric Fever. 2. A New System of Ventilating Sewers and Drains.

In the evening a *soirée* was held in St. Andrew's Hall, which was well attended.

Before quitting Norwich we may as well mention a few of the principal objects in this interesting city. First of all is the Cathedral, with its almost unequalled architecture of the Norman and early English periods, a volume of history in itself, which time seems feeble in its attempts to destroy. Then there are the new sewerage works and farm, filtering-beds, &c., capital illustrations for those who wish to see practically carried into effect one of those important problems which have for some time past occupied so much of the attention of sanitarians. Then there are the factories, none of them pigmies, and one the largest by far of its kind in the world—we refer to the mustard and starch manufactory of Messrs. J. and J. Colman, over which we were courteously shown and the whole processes described to us—from the white and brown mustard seed after it is threshed, through its various stages of crushing, separating the husks, and pounding with a hundred steam mortars until the refuse came out in oil-cakes for cattle and manure, and the mustard-oil was expressed for medicinal purposes, of the value of which our readers are well aware. Mustard has for a long time past been one of those puzzles which the framers of that excellent measure the Adulteration Act and analysts have been unable to deal with. Knowing from experience that the public could not endure mustard pure and simple, manufacturers determined at all risks to make the article what it always had been, and in order to avoid any infringement of the Act, we observed upon the packets we took up, printed in type big enough for any one to see, "this preparation is an admixture of pure mustard with farina and choice condiments;" whilst upon other packets we noticed the word "genuine." Upon inquiring what was the general taste with regard to the two articles, we were informed that the public would not have the "genuine" at any price, the sale of which was infinitesimal in comparison with the mixed article; but that they issued it in this form in order to comply with the Act, and that there should be no difficulty in the way of obtaining the pure article wherever it was preferred. We think this course both fair and honourable, and the committee which recently sat upon the Adulteration Act appear to hold views in the same direction. It is one thing to prevent dishonest traders dealing fraudulently, and so to protect the public from slow poisoning; it is another to compel an honest manufacturer to make an article which will not sell, and which, when so made, is both inferior and distasteful. A visit to the manufactory of Messrs. Colman has removed from our minds many little prejudices, and we would suggest that a deputation from the Food Committee of the House of Commons should pay an unexpected visit to a manufactory here and there; to our minds they would get more useful hints than by taking the evidence of all the experts in the kingdom.

Having gone beyond our intention with a description of some of the points of interest to which we were attracted, we must express briefly the pleasure our visit to the Norfolk and Norwich Hospital gave us; it is certainly one of the best of provincial hospitals it has been our lot to enter. There were also several minor and special hospitals, museums, factories, &c., which time did not permit us to visit; but on the whole, we were both pleased and edified with what we saw in the city of Norwich, and regret that so excellent a programme was so badly patronised, and the forty-second meeting of the British Medical Association so meagrely attended.

## Correspondence.

### CROUP.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A few remarks on this subject from an experienced mother and home nurse may not be unacceptable. Your correspondent, last week, asks for information as to the ages when the attacks usually commence and disappear. I believe he is correct in supposing that the disorder is rare previous to the age of two years, but that immunity may be due to the greater care taken of very young children in protecting them from cold: at two years of age they begin to run about, and may get their feet wet, stand in draughts of air, or run out of the house without sufficient clothing in winter; this is very likely to happen with the children of the poor. With reference to the period in a child's life when the attacks from this dangerous disorder may be expected to cease, I know that they may take place after the seventh year; one of my own children had a very severe seizure when he was in his tenth year. The following extract from a communication which I contributed to one of your contemporaries may be of some use to your readers who are interested in the subject. I may say that I have never had occasion to call in medical aid after my first experience of the disorder, but I was always able to subdue an attack in an hour, by applying remedies immediately upon hearing the first sound of the cough:—

Croup may be regarded as an insidious disorder, because in very many cases the first notice of it is the peculiar cough—never forgotten when once heard—which tells that the enemy has made considerable advantage, and that prompt measures are needful.

Most maladies—especially those of children—are indicated by certain symptoms before the actual disorder develops itself, thus restlessness, languor, loss of appetite, and numerous little signs will in general point out that all is not right; but with croup it is not always so—the child will go to bed apparently in its accustomed health and spirits, after having enjoyed its food and played about as usual during the day. In a few hours—generally about midnight—a croupy cough will arouse everyone within hearing.

The sound of this cough is not easy to describe to those who have never heard it; I believe it is generally understood to have a harsh, metallic sound, with some resemblance to the bark of a dog; this comparison, singular and vague as it is, gives as good an idea as it is possible to convey by description.

It is often difficult to discover the precise cause which has induced an attack of croup, especially when it comes on without those premonitions which usually augur a cold; in two instances I have been able—after taking pains in the matter—to trace a croupy cough to peculiar causes which ought to be made known; the child, on one occasion, had been allowed to sit with its back to a window for some time; the window frame although shut down, was not well protected from the weather, for upon placing the hand over the crevices, a great draught of air was perceptible; the other attack came on after the child had been taken out for a drive, and though in a close carriage, the little one had been sitting (on its nurse's lap) at an open window facing the wind.

These are "trifles"—so called—but when disregarded they become formidable in their results. The merest trifles have power in them to produce mischief, if not guided by intelligence nor superintended with care; and children who have once suffered from an inflammatory attack of the throat or chest, are thereby more susceptible, and require to be scrupulously guarded against any invasion from (apparently) insignificant quarters.

Where there may be reason to fear that a child—who is subject to croup—has taken cold and an attack threatens, it may be warded off by giving small repeated doses of ipecacuanha wine during the day. This is not the place, nor is it the province of the writer to prescribe; the family should therefore be consulted beforehand as to the precise quantity of ipecacuanha, in what proportion to be diluted, and how often to be taken.

The chest and back should be well rubbed with a liniment at bed-time, and the usual little comforts and attentions for a cold—not necessary to be enumerated—will mostly complete the preventive treatment.

When, however, it is found that croup has actually set in, an emetic should be given without delay; and unless some

person of judgment can undertake the management, the wisest plan is to send for the doctor at whatever time of night. I have used the word "judgment," and have avoided the hackneyed and fallacious term "experience," because what is really wanted at such times is a person possessing a *knowledge* of the disorder, and the necessary capabilities to put such knowledge into practice.

The cough coming on at an unreasonable hour of the night, is too often made an excuse for neglecting it; the nurse perhaps unwilling to arouse herself or to disturb others, she waits and waits and does nothing, with the vain hope that the attack will "go off"—the croup when once set up does not subside without active remedies: every minute of delay adds to the mischief. A homely proverb tells us that "delays are dangerous," and in nothing are they more dangerous than in the neglect of prompt measures at the first appearance of symptoms which are truly premonitory.

In the Registrar-General's Quarterly Report, just issued, remarking on the high death-rate amongst children, it is said, "*I fear that often little notice is taken of illness until secondary symptoms appear, when medical aid is too late.*"

All persons who have the charge of little children, should inform themselves of the best means to adopt where the earliest symptoms are noticed; it should be known by all mothers and nurses, that in croup a false membrane, or lymph, forms in the windpipe—increases very rapidly—impedes respiration—and if not dispersed or removed, would finally cause suffocation. Muscular action of the throat is therefore of the greatest importance; hence the value of emetics. I have seen the effect hastened by being given in warm water; it is also very beneficial to rub the chest, and between the shoulders, gently but *determinately*. A liniment may be used, but the hand rubbing only is very effectual, if properly done; it helps to dislodge the obstructing substance in the windpipe, and is then more easily forced up by the effort of coughing.

There is an impression prevalent that children become free from this disorder when they complete their seventh year, but this idea is erroneous and dangerous.

In some "Hospital Notes on Croup," lately published in one of the leading medical journals, numerous cases are given in which tracheotomy was performed, and some of the patients were stated to be at ages considerably above seven—viz., ten, eleven, and there were two at sixteen years. In many of the cases which proved fatal, the patients had been neglected for several days, and their symptoms becoming urgent, they were taken to the hospital in an all but hopeless condition.

I believe these and similar cases may be considered exceptional (the greatest number of croup attacks happening at the age of five), but they are sufficient to take warning from, for many persons relax precautions at the seventh year, under the idea that all danger has then gone by.

I am, Sir, yours obediently,

MATER.

## Medical News.

**Apothecaries' Hall.**—The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Aug. 6th:—

Brady, Owen Cornelius, Vernon Road, Birmingham.  
Mitchell, Charles Joseph Carter, Kempston, Bedford.

The following gentlemen passed their primary professional examination on the same day:—

Lewis Berkley Calcott, Robt. Haselden, Walter Relf Pearless, and Alfred Upton, St. Bartholomew's Hospital;  
Sidney Geo. Parkinson, St. Mary's Hospital.

**Scene in a Lunatic Asylum.**—An extraordinary action to recover damages for injuries sustained through alleged negligence was tried last week at the Bristol Assizes before Mr. Justice Brett and a special jury. The plaintiff is Mr. Broad, the son of a retail merchant residing at Falmouth, and the defendant is Dr. Lyle, the resident medical superintendent of the Wanford House Lunatic Asylum, near Exeter. In 1872 the plaintiff, owing to his father's placing some bar in the way of his paying his attentions to a certain young lady, became very ill, and ultimately insane, exhibiting a decided suicidal

tendency. He was at first removed to a farmhouse and attended by two keepers, but subsequently it was found necessary to send him to a regular asylum. He was accordingly removed to Wanford. He was very mad whilst there, and attempted to jump from the window on one occasion. In December, 1872, early one morning, the door of the room in which the plaintiff was confined was left unlocked by the attendant, who had brought him his clothes, and plaintiff escaped, made his way to one of the upper galleries, smashed the window, and then leaped out, falling a distance of thirty feet. He was very much injured, but the effect of the shock was to restore his reason. Paralysis was the result of the injuries received from the fall, but his reason had been perfect ever since. Medical evidence was given to show that, in all probability, he would never recover the use of his limbs.—Mr. Lopes, Q.C., in defence, submitted that the defendant was merely the servant of the committee for the institution, and in no way liable, and that if he were to be held so, it would be tantamount to his ensuring the proper discharge of every duty by all the people engaged in the establishment. He also submitted that the action should have been brought within twelve months, which it had not, and that notice of action should have been given.—Mr. Cole, Q.C., submitted that there was a statutory duty cast upon defendant to carry out the rules of the institution, and he had neglected to do so.—Mr. Justice Brett said the evidence showed that the defendant had given every order that was necessary, and no want of compliance with those orders had ever been called to his notice until after this occurrence. He was of opinion there was no evidence of neglect for which defendant was legally responsible. Plaintiff was, therefore, nonsuited, but leave was given to him to move for a new trial on the ground of misdirection.

**List of Indian Medical Candidates** who were successful at both the London and Netley examinations, having passed through a course of instruction at the Army Medical School at Netley, August, 1874:—

	No. of Marks.		No. of Marks.
Leckler, H. M. ...	5,868	Malcolm Smith, G. J. ...	4,465
Corbett, J. L. ...	5,626	Lancaster, J. ...	4,450
Browne, S. H. ...	5,385	Yeld, H. P. ...	4,300
Mair, E. ...	5,339	Fullerton, J. C. ...	4,075
Benson, P. H. ...	5,208	Warden, C. J. H. ...	4,055
Armstrong, J. ...	5,125	King, W. G. ...	4,003
Warder, R. ...	4,825	Fatterson, D. A. ...	3,980
Dawson, L. R. ...	4,798	Wilkins, J. S. ...	3,908
Shircore, J. C. ...	4,650	Barren, W. A. ...	3,602

**The Medical Education of Women.**—Miss Philomene Ratincx of Antwerp has passed a brilliant examination in the anatomical sciences before the combined jury of Ghent and Louvain for the faculty of medicine. She has also obtained the royal diploma for the treatment of clubfoot. Two Circassian ladies, at the Russian Academy of Medicine and Surgery, propose to return to their own country to practise the profession when they have taken their degrees.

**The King and Queen's College of Physicians and Female Licentiates in Midwifery.**—Miss Ellen Greenstreet presented herself for examination on the 6th instant, and passed the examination in a very creditable manner. Miss Greenstreet was lady superintendent of Sir Patrick Dun's Hospital. The question whether this diploma is or is not registerable may be raised at any time. There is little doubt, however, that the diploma is a registerable qualification.

**College of Physicians, Ireland.**—At examinations held on Aug. 4th, 5th, and 6th, the following gentlemen obtained the licences in Medicine and Midwifery:—*Medicine*: Arthur Henry Cole Dane, Edward Michael Angelo Hogan, Agmon Blathwayt Vesey. *Midwifery*: Samuel Thomas Gordon, Agmon Blathwayt Vesey.

**Bequests to Medical Charities.**—By the will of Thomas Banting, late of Worthing, Sussex, who died on June 20, the testator bequeaths to the Royal Hospital for Incurables, Putney; the British Home for Incurables, Clapham; the Idiot Asylum, Earlswood; the Worthing Infirmary, the Sussex County Hospital, St. Mary's Hospital, Paddington; the Westminster Hospital, King's College Hospital, the Middlesex Hospital, the Charing Cross Hospital, the Lock Hospital, Harrow Road; the West London Hospital, the Consumption Hospital, Brompton; the Cancer Hospital, Brompton; the City of London Hospital, Commercial Road; the Hospital for Sick Children, Great Ormond Street; and the Great Northern

Hospital, Caledonian Road, £1,800 each; to the Paralytic and Epileptic Hospital, Queen's Square; the Royal Westminster Ophthalmic Hospital, the Orthopaedic Hospital, Oxford Street; and University College Hospital, £900 each; to the City of London Truss Society, £450. The legacy duty, amounting to upwards of £6,000, on all these legacies is to be paid out of the estate, so that the charities will get the amounts given to them clear and free from all deductions. The testator gives legacies to several non-medical charities besides, amounting to about £30,000, also to members of his family and others, and the residue of his property is to be applied and disposed of by his executors to the best of their judgment, with a view to help convalescent persons needing the beneficial climate and other advantages of Worthing, and he desires the charity to be called "Thomas Banting's Memorial."

**St. Andrew's Medical Graduates' Association.**—The Committee appointed at the last meeting of the members, held December 30th, 1873, met on Friday, July 31st, at 12 Hinde Street, Manchester Square. Present: Dr. B. Ward Richardson (in the Chair), Drs. Ballard, Cholmeley, Christie, Cleveland, Paul, Sedgwick, Wynn Williams, and the Hon. Secretary. The treasurer reported, that after payment of the working expenses, and the cost of the Transactions, there still remained a balance in his hands of £60 14s. 1d., notwithstanding the fact that 78 members had still omitted to pay their subscriptions. Dr. Sedgwick moved, and Dr. Cholmeley seconded: "That a sum of twenty-seven pounds be voted out of the surplus for the 'Mrs. Day Fund.'" Carried unanimously. Dr. Richardson moved, and Dr. Sedgwick seconded: "That a sum of ten guineas be applied out of the surplus to give a trifling recognition to Dr. Paul for his valuable services as treasurer during the existence of the Association." Carried unanimously. Dr. Wynn Williams moved, and Dr. Ballard seconded: "That the balance of the surplus be placed in deposit in the names of Drs. Richardson and Paul to meet any future contingencies arising in connection with the University Committee of the Association." Carried unanimously. It was also resolved that subscriptions at present unpaid should be forwarded to Dr. Paul for the same purpose. The proceedings terminated with a vote of thanks to the chairman.

**The Temperance Breakfast.**—A breakfast was given at the Royal Hotel, Norwich, on Friday, to the members of the British Medical Association, by the President of the National Temperance League, who was accompanied by Major-General F. Eardley-Wilmot, F.R.S., and the Rev. Canon Lee Warner. The venerable President of the League (Mr. Samuel Bowley) welcomed his guests, about 100 in number, in a short but genial and temperate address, which was entirely free from dogmatism, and the other two members of the deputation followed suit in a similar spirit, completely disarming opposition by the candour and courtesy with which they presented the claims of a movement that has often been sadly injured by the censorious spirit in which it has been advocated. The first speaker was Dr. T. Milner Fothergill. An animated discussion ensued, at the conclusion of which Dr. Gibbon moved, and Dr. Tuke seconded, a vote of thanks to the Chairman and the National Temperance League, which was carried by acclamation, and the proceedings, which had been conducted through, and with great good feeling, were then brought to a close.

## Gleanings.

### Experimental Researches on the Movements of the Uterus.

In an analysis of German works, Dr. Puech publishes the principal results of the experiments of Oser and Schlesinger as to the influence of suppression of respiration and arrest of circulation on the movements of the uterus, and on the rôle of the nervous system in these phenomena. The experiments were performed on young rabbits not yet pregnant, but capable of becoming so.

In these animals the uterus is immobile under regular respiration, but is subject to spontaneous movement after gestation.

The following are the chief conclusions:

1. The suspension of respiration provokes, after ten to thirty seconds, general contractions of the uterus. So soon as respiration is re-established the old order returns.

2. Compression of the aorta, produces, at the end of 80-100

seconds, a general contraction of the uterus. Compression of the aorta in post-partum hæmorrhage is thus perfectly justifiable.

3. The contractions of the uterus which supervene a few seconds after arrest of respiration may not be considered as a peripheric irritation of the organ produced by the special action of the venous blood. If arrest of respiration be combined with compression of the aorta, contractions supervene at the end of 10-30 seconds, and not slowly as after simple compression of the aorta.

These phenomena are always influenced by troubles of the nerve centre.

4. Copious hæmorrhages determine also, at the end of several seconds, generalised contractions of the womb, explicable solely by irritation of the nerve centres. To refute the objection that anæmia may be the cause of these contractions, the aorta or vena cava were compressed as if to prevent hæmorrhage, which did not occur until 15 seconds after section of the carotids, when the uterus was strongly contracted.

5. The obliteration of the four cerebral arteries provoked likewise, after several seconds generalised uterine contractions. Ligatures applied so as to lose as little blood as possible produced a result identical with that of suspension of respiration.

6. After section of the spinal marrow contractions of the uterus did not supervene more speedily on suspending respiration than on compressing the aorta; hæmorrhage and occlusion of the cerebral arteries were now without effect on the womb.

What now necessarily follows from these experiments is the fact that if serious interference with the cerebral circulation caused uterine contraction, the lack of communication between the uterus and the brain should suppress these contractions, every hæmorrhage too, no matter how great, should remain without effect.—*Gaz. de Joulin, Gaz. des Hôpitaux.*

### Transfusion of Blood in the Insane.

PROF. MEYNER (Wien. Med. Presse) states that the operation of transfusion was frequently performed in England in the seventeenth century in patients suffering from mental affections, but that it could not be supposed that in such cases, even under the most favourable circumstances, the operation would be attended with favourable results.

In cases of melancholia, however, it might be possible to look for a favourable result from the operation, since the transfused blood might act as an irritant, and, like febrile affections, cause an intermission of the state of melancholy. In three cases in which the operation with defibrinated blood was performed by Redner, the pulse rose from fifty to eighty beats per minute, and two of the patients, half an hour after the operation, felt better, and were more cheerful; but this improvement was but transitory. A quarter of an hour later the pulse could scarcely be felt; vomiting, micturition, and defecation took place, followed by a chill of violent character, and fever of three days' duration.

### Injurious Effect of Human Milk upon Dogs.

M. DEVILLIERS stated in a report read before the Académie de Médecine on this subject that the researches which he had made proved human milk to possess the quality of rendering dogs rachitic.

Advantage had been taken of this circumstance in the employment of the milk of dogs for the nourishment of young children suffering from rachitis. What the result of this treatment proved to be is not stated; but in the discussion which followed the reading of M. D.'s report it was remarked that this injurious action of human milk had already been observed in cases where young women had used puppies for "drawing the breast." The animals were observed under these circumstances to succumb speedily.—*Bull. Gén. de Thérap.*

### THE CANCER HOSPITAL, LONDON (founded 1851).

There is a VACANCY at this Hospital for a RESIDENT HOUSE SURGEON and REGISTRAR. Candidates must be unmarried, registered Members of the Royal College of Surgeons of England, and thoroughly conversant with the use of the microscope. The Honorarium 100 guineas per annum, with Board and Residence. Applications with Diploma and Testimonials to be addressed to the Chairman of the Weekly Board, 167 Piccadilly, W., on or before August, the 27th next.

**MEDICAL REGISTRATION (SCOTLAND).**—Notice is hereby given, that the Scottish Branch of the General Council of Medical Education and Registration, having appointed RICHARD INGLIS, M.D., to be Medical Registrar for Scotland, the Office has been removed from 28 Albany Street to 33 Albany Street. Office hours, 12 to 3; on Saturdays, 11 to 1. Edinburgh, 4th August, 1874.

### LECTURES ON BRIGHT'S DISEASE, WITH SPECIAL REFERENCE TO PATHOLOGY AND TREATMENT,

By D. CAMPBELL BLACK, M.D.,  
One of the Physicians to the Hospital.

#### LECTURE VII.

(Continued from page 149.)

**Prognosis.**—As a general rule, it may be laid down that in proportion to the vascularity of an organ, so are the chances of structural changes following inflammation, and the persistence thereof. Acute inflammation of the kidney is at all times an affection of considerable gravity. The gravity of the attack may be rationally estimated by the extent to which the function of the organ is interfered with, and this may reveal itself by departures from the quantity and quality of the fluid excreted. In general, then, if the amount of urine be considerable, the quantity of albumen contained in it small, the specific gravity not far from normal, if there be few blood globules—these constitute a favourable indication. Sometimes, though very rarely, cases in which the urine presents little variation from that of health terminate very abruptly in death, while cases in which the contrary condition exists terminate favourably.

But the state of the urine alone does not suffice in forming a prognosis; the condition of the various organs of the body must be examined, and due weight be accorded to the result of the examination.

The cause of the nephritis must also be taken into consideration. Mechanical albuminuria—static congestion of the kidney—as in the latter months of pregnancy, may be looked upon as the least serious of the various forms of albuminuria. That following scarlatina, if properly treated, is not usually serious. If death does not take place within the first fifteen days, a favourable prognosis may be entertained.

In the case of persons frequently exposed to cold and addicted to alcoholic indulgences, an unsuspected chroni-

nephritis may take on the symptoms of an acute nephritis. The prognosis in such a case would be correspondingly grave.

The persistence of albumen in the urine after the disappearance of dropsy is an unfavourable sign; an acute attack frequently supervenes, which ends in intractable structural changes.

Should the nephritis be due to an exposure to causes which have been removed or combated by treatment, and the albumen gradually disappear, and the dropsy disappear in a corresponding manner, a favourable termination may be predicted. Exceptions to this, as to all other rules, must be held as possible. Nephritis consequent on scarlatina, if promptly recognised and appropriately treated, terminates favourably in the majority of instances.

From what has been already advanced it will be obvious that the presence or absence of tube casts, their nature, and the condition and quantity of the urine, must receive attention likewise.

The prognosis in cases of *chronic nephritis* is of the greatest gravity. The termination of the vast majority of such cases is unfortunately in death. The duration of the affection will depend on the gravity and extent to which the functional derangement of the kidney exists. Hence, if the quantity of albumen passed in the urine be small, capable of being restrained by medicinal agents, or the loss be compensated by careful and appropriate regimen, if dropsy be inconsiderable or have disappeared, if the urine approach its normal specific gravity, and if there be no complication of internal organs, the patient may live a long time, even with considerable structural disorganisation of the kidney.

Dr. Gregory mentions the case of a man who suffered from dropsy depending on renal disease for the long period of *thirty years*. On admission into hospital the urine was found highly coagulable; its specific gravity was 1020, and but 12 ounces were voided during the twenty-four hours. Eleven days afterwards the quantity secreted amounted to 44 ounces, its specific gravity was 1018, and contained no albumen. During the patient's stay in hospital the amelioration in his condition was very striking.

In *chronic nephritis* the size and nature of the tube

casts are of weighty significance relatively to prognosis. Large granular and large hyaline casts indicate, as we have seen, an advanced condition of renal degeneration, that contraction of the kidney is proceeding; and the greater the number of large tubes, so may the rate at which structural changes are proceeding be estimated.

In direct proportion to the size and number of tube casts, so likewise will the specific gravity of the urine be found to be diminished, and its contained albumen augmented.

The greater the quantity of albumen in the urine, the greater the gravity of the case. Dr. Christison, however, thinks that the contrary obtains.

Fatty tube casts, with fat cells in the urine, indicate advanced disease; yet recovery has taken place even in cases thus far advanced. Dr. Johnson has seen recovery in cases where fat cells had existed in the urine continuously for many weeks, and after albuminuria had existed for two or three years. The same authority relates the case of a medical man who suffered from albuminuria, more or less, during thirty years.

A marked augmentation of urine often coincides with the disappearance of dropsy and the diminution of albumen in the urine. Occurring in the comparatively early stages, this must be regarded as a favourable sign; but in later stages an augmentation of the urinary secretion indicates rather advanced desquamation of the tubes, and is of correspondingly serious augury. Fatal cerebral symptoms are often preceded by a diminution or complete suspension of the urinary secretion.

Concomitant affections of other organs will necessarily complicate and add to the gravity of chronic nephritis.

*Retrospective Summary.*—In ultimate composition living animal structure consists of minute bodies, termed molecules of organisation, and are divisible into three kinds, nitrogenous, fatty, and mineral.

From these molecules are formed cells, through whose agency, and by properties peculiar to them in the vegetable as well as in the animal kingdom, are effected what are termed the organic processes, viz., those of secretion, assimilation, and excretion.

By a cell is understood a spheroidal body, having a wall or envelope, and containing material termed protoplasm, which may be regarded as the structural unit of the organism. In the higher organisms each cell contains a round central body, termed a *nucleus*. At the bottom of the animal scale, however, all the phenomena of life are exhibited by masses of protoplasm containing no nucleus.

Cells may be divided into—(1) *Centres of nutrition*, which are merely nucleated cells, from the nucleus of which successive broods of young cells are developed. The function of a germinal centre is to withdraw from the blood material of nutrition for the repair and construction of the special organ or texture in which it may be situated. The original centre of nutrition—that from which the whole organism is formed—is the germinal spot of the ovum. (2) *Secretory cells*. It is the function of the secretory cell to elaborate a new compound required for ulterior purposes in the economy; for instance, to facilitate assimilation, digestion, or locomotion. (3) *The Excretory cells*. This variety differs from the former in that their function consists in the removal of effete and useless material—material which, if retained, would react upon the system as a poison.

All cells are separated from the blood simply by the interposition of a thin membrane.

Each cell possesses a special property, according to the gland or structure in which it is situated. Thus, while no structural peculiarity is recognisable, the liver cell secretes bile, that of the sublingual and submaxillary gland saliva, and that of the mamma milk.

Secretion appears to take place between the nucleus and cell wall, and is evidently the product of the nucleus.

Cells possess three essential properties, viz., that of vital selection—whereby each cell appropriates according to its special wants—osmosis, and chemical combination.

To produce healthy structure to replace the waste of

tissue, the protoplasm supplied to the germinal centre must be suitable or pure, and this will depend on the condition of the blood from which it is derived.

Given healthy blood, healthy protoplasm is elaborated by the germinal centre, and healthy tissue to replace that which has become effete, and is being converted into ultimate products by oxidation.

In order, likewise, that secretion and excretion be normal, the blood supplied to the secretory and excretory cells must, in like manner, be healthy. Otherwise perverted chemical combination ensues, leading to structural changes in the cell and ultimate disorganisation of the organ.

The normal correlation of cell and blood may be disturbed in a twofold manner. In the first place, the blood may be healthy, but its supply may be deranged; hence disordered circulation even of pure blood may induce malnutrition and mal-secretion and excretion. In this case the property of *osmosis* possessed by the cell is the first to suffer. In the second place, perverted correlation of cell relatively to the blood may be primarily due to blood impurity, leading, however, in like manner, to ultimate disorganisation in consequence of abnormal chemical changes.

The circulation of the blood is under the influence of the nervous system. The motor system carries on the circulation; the sympathetic regulates the tonicity of the minute arterioles. Section of the sympathetic, or transient impressions exercising a paralysing influence upon it, is followed by congestion of the particular organ or structure to which the portion of the nerve so influenced is supplied. Hence the influence of cold upon the loins, by acting upon the splanchnic nerves, may induce simple nephritis, which may, of course, proceed to ulterior pathological changes, ending in destruction of the kidney and death. (*Vide* pages 290 and 291.)

The pathological changes which the kidney undergoes in chronic nephritis may, in general terms, be said to be either inflammatory or fatty. The inflammatory consist in congestions and effusion of coagulable lymph, with contraction. The fatty in degeneration (*vide* page 463) of the protoplasm of the cells and structure of the kidney. Due oxidation of tissue, we have seen, is essential to healthy repair and secretion. Decarbonised blood will effect retrograde changes of tissue, resulting in the formation of fat. Alcohol is a hydrocarbon; excessive indulgence in it causes the blood to be surcharged with carbon—an effect striking enough in the appearance of the habitual drunkard. Hence observation and experience abundantly prove that amongst the most frequent causes of chronic nephritis and cirrhosis, is recognised chronic alcoholism.

*Treatment.*—In the treatment of inflammation of any portion of the body the indications will vary according to the stage of the disease, and consequently the period at which the patient comes under observation. If it be the initial stage that we are called to treat, we attempt to remove the cause, relieve local congestion, and thus restore the normal circulation and function of the part. Should the disease have passed into the secondary stage—viz., that of effusion, in addition to the foregoing, we endeavour to stimulate the absorption of the effused products. If evidences of structural changes exist, and if the function of the organ be impaired, endeavours must be directed with a view to repair, and of imposing vicarious duty on other organs.

There is perhaps no disease in which the fashionable waiting-upon-death of modern physicians is more to be reprehended than in the treatment of acute nephritis. If the history of the case furnish, as a presumable cause of the affection, an exposure to cold or damp—and the latter you frequently observe at this hospital, in this relation, in the cases of miners, who present themselves suffering from anasarca, which they are unable to account for—I say, if there be a history of exposure to cold or damp, with albuminous urine, with or without the other indications of nephritis, general bleeding should at once be resorted to. It is perhaps the most potent means of fulfilling the

indications which the first stage of inflammation furnishes. The quantity of blood removed ought to bear a proportion to the intensity of the febrile disturbance and the suddenness of the accession of dropsical symptoms.

That general bleeding has done good in these cases the testimony of competent and reliable physicians abundantly proves, and that it will and ought to do good reason teaches us to believe. The reaction against general bleeding limits us to one of two conclusions: either Nature cured inflammatory affections in times gone by, and the testimony and observation of the writers of these times are worthless, or the diseases of the one age are not curable by the means adopted in the other. To evade this peculiar dilemma the doctrine of change of type has been propounded—a doctrine I have no hesitation in pronouncing, one of the most melancholy that could be advanced to flatter conceit, palliate scientific imperfection, and condone a contemptible subservience to the caprices of fashion.

Nature's laws may change, but man's judgment, never!

The blood, we have seen, in acute nephritis, is surcharged with fibrine, and effusion of fibrine into the inflamed organ is one of the complications especially to be guarded against. General bleeding, it is well known, diminishes the amount of fibrine in the blood.

Should the symptoms be less severe, cupping over the region of the kidneys may take the place of bleeding, or after venesection may have been practised, the withdrawal of blood by means of cupping may follow, according to the indications of severity.

Should these methods be deemed too severe, blood may be withdrawn by means of leeches applied to the loins.

In either case the bleeding may be subsequently encouraged by the application of large linseed meal poultices, which may be advantageously covered or mixed with laudanum, or by hot fomentations applied to the loins. The poultices or fomentations should not be permitted to become cold, but should be repeated on the slightest fall of temperature. An excellent method of applying heat, with a regulated temperature, is supplied by the india-rubber bags suggested by Dr. Robertson, of the Town's Hospital, Glasgow. Alternately with these measures hot water baths should be employed. A feeling of oppression or faintness sometimes induced in this manner is to be guarded against. The skin should be carefully dried after the bath, the patient replaced in bed well covered, and the action of the skin encouraged by small doses of antimonial or ipecacuan wine, frequently repeated, small doses of compound ipecacuan powder, or James's powder may be substituted, or alternated with the former. Under all circumstances, exposure to change of temperature must be scrupulously guarded against. These are the methods by which congestion of the inflamed kidney is most likely to be relieved.

But should the patient not have been treated in the earliest stage—a circumstance indeed of the most frequent occurrence—in addition to the renal congestion there exists more or less effusion of coagulable lymph; this we endeavour to get rid of by stimulating absorption. Of all the remedies that stimulate the absorbents, none possess that property in a more marked degree than the preparations of iodine and mercury. Furthermore, mercury fulfils another important indication in the treatment of nephritis, it diminishes the amount of fibrine in the blood. And why should mercury diminish the amount of fibrine in the blood? It stimulates the function of the liver, and we know that fibrine is lost to the blood in passing through the liver, its nitrogen combining, as we have seen, with lower products of oxidation to produce urea. The more active the function of the liver the greater consequently will be the destruction of fibrine, and the amount of urea formed. In cases of nephritis, I am bound to tell you that with the vast majority of practitioners mercury is a drug tabooed. That it should be so I believe to be one of the many beliefs current among medical men, unfounded on reason, and contrary to the experience of competent observers. If you ask why, if mercury has a beneficial effect in other inflammatory

affections, it should not have an equally beneficial effect in nephritis, you are simply informed that in these cases it speedily causes salivation. I am not disposed to assent even to the truth of the objection; but even assuming it to be true, I answer that salivation is not a serious disease, and it certainly accords with my experience that the administration of mercury has mitigated the most alarming symptoms of nephritis, if it had not actually cured the disease. In the hospital I have given the bichloride of mercury in small doses, 1-16th of a grain, combined with iodide of potassium—a biniodide of mercury soluble in excess of iod. potass. being thus formed—and have satisfied myself that the quantity of albumen in the urine was thereby diminished. In cases of syphilitic cachexia its special indication will be too obvious to necessitate comment.

Recently I saw at the dispensary a boy suffering from nephritis with anasarca, consequent on scarlatina. Grey powder in two grain doses, with one grain of ipecacuanha, night and morning, were prescribed. Œdema of the face had taken place to such an extent that the boy could not see, being unable to open his eyes. There was also very great dyspnoea. I afterwards saw the boy in private. Exposure to cold had evidently aggravated his condition, as pulmonary Œdema had supervened. The treatment was persevered with, with the addition of antimonial wine and liq. ammon. acet., and the boy made a good recovery. In similar cases I would certainly advise grey powder and ipecacuanha, in addition to the treatment already referred to.

It is well to bear in mind that not unfrequently, evidently the worst cases recover, while apparently slight ones unexpectedly and suddenly terminate fatally.

In the more advanced stages of nephritis counter-irritation should be applied over the region of the kidney. As to the nature of the counter-irritant, difference of opinion may exist: cantharides has been objected to from a dread of its causing strangury, and consequently doing mischief; but in view of the fact that tincture of cantharides has itself been employed in the treatment of chronic nephritis, the objection should carry less weight. Rayer testifies to its good effects, though he remarks, "*c'est un remède incertain et qui pourrait être dangereux dans des mains inexpérimentées.*" I should certainly regard it as not only a dangerous remedy, but one whose *modus medendi* would seem to me perfectly inexplicable.

Should the application of cantharides to the loins be dreaded, counter-irritation may be established by tartar emetic ointment, croton-oil, iodine, &c.; and while the skin is tender mercurial or iodine ointment should be judiciously applied.

Instead of the ordinary counter-irritation, the actual cautery may be applied, or setons may be established for a like purpose. With a view to vicarious elimination of urinary constituents the bowels and skin should be acted upon. On no account would I advise you to have recourse to saline purgatives, for a considerable portion of the salines are eliminated by the kidney. Medicines which are eliminated specially by the bowels are therefore to be preferred. Elaterium may be given in doses of from  $\frac{1}{4}$  to  $\frac{1}{2}$  a grain in combination with colocynth pill mass, combined, should there be no contra-indications, with a little mass. pil. hydrarg.; scammony, gamboge, and castor-oil may also be beneficially employed.

The skin is best acted upon by baths, antimonials, and liq. ammon. acet.

Diuretics are actually employed at the present day in the treatment of acute and chronic nephritis—on what basis in reason, or common sense, I have ever failed to comprehend; I have always regarded it as an axiom in the treatment of inflammation, that rest to the inflamed organ is of the first importance. As well, in my opinion, command a man suffering from double pneumonia to leave his bed and take a three mile race as give stimulating diuretics in a case of nephritis. These diuretics *do act as such*, by causing transient congestion; and how they can

act favourably in nephritis may well tax the fertility of the most luxuriant imagination.

Diluents, however, may be employed with advantage; for if it be true, as we have postulated, that the solid constituents of the urine are separated in the convoluted tubes, then diluents in passing over the surface of the secretory glands would facilitate their removal by solution, as happens in the normal condition.

Scarifications of anasarctous parts is, as a rule, not to be advised; I have frequently seen diffuse erysipelatous inflammation supervene in consequence. The application of blisters for the removal of serum is a practice still more to be reprehended. What more likely than that an intractable slough should follow the application of a blister to a part with such depressed vitality?

Secondary affections must be treated on general principles. The diet of the patient should be of a nutritious description, consisting of animal food, milk, &c.; alcoholic drinks should be strictly forbidden.

Notwithstanding your utmost endeavours, nephritis will prove of the greatest gravity, but you will be acting worthily of your profession and of your duty to society, by treating this and all other diseases on the general principles of our art, established by time, talent, and the experience of our predecessors, to the extent that these harmonise with your mature judgments, condemning alike the influence of mere fashion and the sacrifices that a manly adherence to truth always entails.

## REPORT ON SYPHILIS.

By C. R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.,  
Senior Physician to the Metropolitan Free Hospital.

### DIAGNOSIS OF TERTIARY SYPHILIS OF THE TONGUE.

THERE was, it may be remembered, during last session, a very interesting discussion in the Royal Medical and Chirurgical Society of London on the question of disease of the tongue, in which certain new views were enunciated by Mr. Fairlie Clarke as to the diagnosis between syphilitic tongue and the disease called psoriasis, or tylosis of the tongue.

Dr. Alfred Fournier has recently (*France Médicale*, July 4) delivered a lecture at the Lourcine Venereal Hospital of Paris which is sufficiently to the point to make it worth translation.

In this case, as in the majority of lesions, says the lecturer, about which we have to speak this year, the practical question—the question which is of itself weighty—is that of the diagnosis. And here, more than elsewhere, this question demands careful study, for the majority of the lesions which may be confounded with tertiary affections of the tongue are lesions rather rare, ill-known, only described up to this time in monographs, and not yet having attained city-rights among the classics. You shall judge.

First of all, I shall just allude, in passing, to indurated chancre of the tongue, as a lesion which may possibly be confounded with those which occupy me.

Doubtless the lingual chancre may effect some objective resemblance with certain tertiary lesions which are indurated and circumscribed, like those, for instance, we have described under the term *glossitis*, ulcerating and plastic, but it will easily be distinguished from it by a deeper analysis of the symptoms, and especially by the morbid evolution.

The chancre, firstly, is not an ulcer, at least, in general, it is most habitually an erosion. Besides, it has a significant swelling of the glands, which is absent in tertiary syphilitic affections. Lastly, and above all, the chancre is a lesion which inaugurates syphilis, which serves as the forerunner of all the other syphilitic lesions; whilst tertiary syphilis of the tongue is a lesion which succeeds to others, and which has had before it quite a morbid series of special accidents. So that it is really with other mor-

bid states that the differential diagnosis of tertiary syphilis of the tongue has to be made—dental glossitis, smoker's glossitis, tuberculous glossitis, and canceroid.

1. *Dental Glossitis*.—We may give this name to certain lesions of the tongue produced by contact with broken teeth at the point where the tongue comes in contact with them.

When a point of the tongue comes in contact with a tooth, broken and rugged, with sharp point, or cutting edge, it inflames and becomes eroded; a knot of chronic inflammation is developed at the point, which is hard and elastic. Erosions continually renewed are produced by the constant contact of the broken tooth, and, at last, after a certain time, by degenerating into a true ulceration.

Now, this ulceration, resting on an indurated base, this ulceration of persistent and chronic character, may very well simulate an ulcerating syphilitic affection; and, in fact, numerous are the errors which have been committed in this matter. I have been assured of this lately by a distinguished dentist, who formerly was an hospital assistant—M. le docteur Delestre, whom I went to consult on this subject. "Not a week passes," he said, "that I am not consulted for cases of this kind, and among the patients I see there are a good number who, although they have never had syphilis, are nevertheless treated with mercury, only on account of these dental ulcerations, which have simply been considered as syphilitic."

It suffices, however, to be warned of the possibility of such an error, in order to avoid it. We will very easily recognise the dental glossitis by remarking the lesion which causes it, that is, the jagged tooth, which is broken in such a way as to ulcerate the tongue.

Circumscription of the lesion, and relation of vicinity with the diseased tooth, this is what should at once point out the diagnosis. As confirmation, let us add that filing or drawing the tooth suffices to get rid of the lesion in a few days. There is not then, truly speaking, any differential diagnosis to make; there is merely the possibility of a rude error to be explained, and when this is recognised, the error will at once be avoided.

2. *Smoker's Glossitis*.—Among the most authentic mischiefs due to tobacco-smoking, there is, you know, to be counted, a stomatitis of a very special character, and one which is wont to affect the tongue principally, and create a glossitis of not less special character.

Well, this glossitis, when it has attained an advanced size, may be confounded with tertiary syphilis of the tongue. Common practice bears witness to this. And, for my part, I certainly see every year a dozen of individuals, who, guilty solely of an exaggerated passion for tobacco, think themselves syphilitic, or have been treated as so, for lesions which tobacco has established in their mouth.

When arrived, indeed, at this high degree, the smoker's glossitis is marked by the following phenomena:—

The tongue is considerably modified in its aspect, it is rough on its surface, and covered with eminences, its edges are irregular, and as if tuberculated; it is covered in the middle part with a sort of whitish pellicle, which is cut across by striæ and furrows directed in all ways; it is indurated to a variable extent, either partially at its edges, or in its anterior third or half; lastly, it is eroded in different points to an extreme degree, truly *ulcerated*. The ulcerations which are then produced, the sole lesions which interest us, are of variable aspect; often they are multiple, disseminated and superficial, not going deeper than the most external parts of the mucous membrane; but sometimes, also, they are hollowed out, and pretty extensive, of the diameter of a piece of 50 centimes, or of an almond, resting on indurated tissue, and presenting a base which is irritated, red or yellowish, of bad aspect, &c. It is in these local conditions that they may, above all, be confounded with ulcerating syphilitic affections.

How, in such cases as these, are we to be enlightened as to the nature of these lesions? By the three following very simple considerations:—

1. History, exaggerated and chronic abuse of tobacco.

2. Age of the lesion and chronicity. We do not come to such an extreme degree of smoker's stomatitis, except slowly, and after many years. The mouth has been affected then for a long time.

3. The co-existence with these ulcers of the tongue of other lesions quite pathognomonic, namely, the *pearly plates* of tobacco.

This name is given to that whitish appearance, that kind of pellicular covering which is smooth and white, and which covers the tongue of old smokers, resembling what the tongue would be when covered with collodion or recently cauterised with nitrate of silver. These pearly plates are not met with in any other disease, even in the affection called psoriasis of the tongue, and are the undoubted witnesses of tobacco glossitis.

Besides, these pearly plates are not only seated on the tongue, they also occupy other points of the buccal mucous membrane, and notably a point favoured by them, where they are never wanting, the internal aspect of the cheeks, quite close to the commissures of the lips.

Thanks to these characters, and to other considerations, which it would be superfluous to mention here (antecedents, and actual syphilitic accidents), the smoker's glossitis is easily distinguished, at least, generally, from ulcerating syphilitic symptoms.

The difficulty is not here; but commences when there are on the same patient two morbid influences—tobacco on one hand, and syphilis on the other.

In such a case, it is often difficult, even sometimes impossible, to make a differential diagnosis.

To say it in passing, nothing is more singular as an accident, and nothing also more obstinate than these complex lesions of syphilis and tobacco on the tongue.

Certain patients come before us in a truly frightful state. Their tongue does not show a square centimetre of normal tissue; it is indurated in its anterior third or half; quite deformed at its edge; white and pearly at certain points; eroded or ulcerated in others, and that for a great extent; contused, with bridles of old scars, and vestiges of old ulcerations; traversed in all directions by erosive striæ or ulcerated and bleeding furrows.

And I would add, nothing more difficult to cure than such lesions, because of the diseased tissues we have to do with, tissues evidently modified in their texture by the inveterate custom of smoking, *cooked* or *smoked*, as M. Ricord used to say, and these cicatricial tissues, which ill lend themselves to a reparatory process, ulcerate anew on the slightest occasion. Hence, necessarily, slow and difficult scarring takes place.

3. *Tubercular Glossitis*.—You know that, under the influence of the tubercular diathesis, there sometimes take place in the mouth some ulcerative lesions, not only analogous, but identical in nature with those of phthisis of the larynx and intestinal phthisis.

This affection, which, clearly pointed out by M. Ricord, has received the name of *buccal phthisis*, chiefly affects the tongue, and is announced by ulcerations of more or less extent, more or less hollowed out, of varied aspect, and sometimes simulating tertiary ulcerated syphilitic tongue.

To differentiate these lesions from ulcerating syphilitic affections there is but little account to be taken of their objective character—that is, of the character of their base, edges, or of the condition or form of the base, its extent, &c., even of those yellowish stains in the neighbourhood, pointed out by M. Trélat as a good character sufficient to determine the nature of the lesion, stains which, besides, are far from being constant, and which, for my part, I have rarely observed. All that is subject to variations, and offers only presumptions which often deceive, so that the diagnosis, in a good number of cases, can only be founded on more general considerations of another kind, such, in fact, as the two following:—

1. A notion of the antecedents and actual symptoms. Has the patient had, or not had, syphilis before? Does he present or not some other symptoms of syphilis?

2. Examination of the constitution. This is the sign *par excellence*—the medical criterium to consult.

Most frequently, indeed, tubercular granulations are produced in subjects already phthisical, who have pulmonary disease, or laryngeal phthisis. In this case the diagnosis of the pulmonary or laryngeal disease is the diagnosis of the tongue disease.

Sometimes, it is true, but more rarely, the lesions are produced as precursors of consumption; but then, if the lung be not tubercular, the individual is so already in the face. He has a tubercular constitution; he has the air and aspect of the tubercular; he has the constitution of tuberculosis, and above all, its antecedents.

And if, which is impossible, this criterium were wanting, the eminently obstinate character and incurability of the glossitis would serve itself to fix the diagnosis. Ulcerating syphilitic affections, in fact, generally are easily cured by the influence of specifics; tubercular glossitis is never cured, and resists all local and general modifiers.

4. *Cancroid*.—Cancroid comes last of all, and requires more than any other lesion to be differentiated from syphilis of the tongue.

What practical interest attaches to the differential diagnosis of cancrroid and ulcerating syphilis of the tongue, I could, if you did not already know it, make you understand in a word, by mentioning this: that on more than one occasion tongues affected with pretended cancrroids have been removed, which were nothing more than gummy tumours, and in which case iodine should have replaced the bistoury; that more than once iodide of potassium has cured lingual lesions reputedly cancerous, and which were, in reality, only gummy tumours.

Of this there are two examples.

A patient, cited by Lallemand, presented a tumour of the tongue, of an aspect such that it had been diagnosed cancer, and very fortunately considered not fit for operation. In despair of the cause, and to administer something, antivenereal remedies were given, and the patient was cured.

Here is another similar observation, communicated by M. Cloquet to M. le Dr. G. Lagneau, and related by the latter in a very interesting memoir on the subject which occupies us. This is concerning a patient who was affected with four gummy tumours of the tongue, each of the volume of a little nut. Under the influence of these lesions, the origin of which went back eighteen months, the tongue had assumed a monstrous development, so that it had been forced from the mouth, and descended to three inches beneath the level of the chin. The patient could not speak in an intelligible way; he breathed and swallowed only with difficulty, and was inundated with a very abundant flow of saliva; so that several physicians had considered the disease as cancerous in character. Sent for in consultation to this patient, M. Cloquet recognised or suspected a syphilitic lesion, and prescribed the bichloride of mercury. Fifteen days later such an amelioration took place that the tongue was already below the lip, in eight or ten months afterwards the larynx was again in its place, and in twenty-eight months the cure was complete.

It is useless to insist, after such cases, on the importance of the differential diagnosis which we have to make. Let us, then, carefully examine on what bases the differential diagnosis of these two lesions reposes.

It is scarcely, except at the period of ulceration, that cancer can be confounded with gummy tumour, for before this time the aspect, form, and hardness of the tumour do not admit of an error being made. Once the ulceration is produced, it is another affair. Doubt is permissible, if not always, at least in certain cases. Let us see by what signs the confusion may be avoided.

We shall have, firstly, certain diagnostic presumptions, derived from the age of the patient, his hereditary predisposition, &c., and the seat of the tumour.

Cancer is, indeed, especially a disease of ripe age, and yet more of advanced age; its maximum frequency is

between 50 and 70 (Auger). Syphilitic lesions are seen generally at a less advanced age.

Cancer is often hereditary, and that in the proportion of one in seven. Nothing like this is seen in syphilitic lesions.

Lastly, a final character may be derived from the seat of the lesion. Cancer affects especially the point and edges of the tongue; syphilitic lesions are produced in preference in the middle portions.

But these are, as you have already understood, only presumptions, and rather hypothetical ones, rather subject to caution to found on them any serious diagnosis.

Far more important are the clinical signs, commencing by the best of all.

The *cancroid* is a tumour; this tumour may be ulcerated on the surface, but is always a tumour. Even in its period of eating away, when the ulcer is depressed from loss of its own substance, the cancer has still a base, like a tumour, and a base quite otherwise appreciable, and far more clearly indurated than the base of ulcerated syphilitic tongue lesions.

The ulcerating gummy tumour, again, is an ulceration without tumour of true nature. It may, indeed, rest on hard tissues, or an indurated base, indurated either by gummy infiltration or inflammatory new growth; but this base does not form a tumour properly so-called, a tumour so distinct as is the tumour of *cancroid*. Do we say that the engorged base of a varicose ulcer forms a tumour beneath this ulcer?

This is the first sign, and also the main sign on which instinctively and from experience we establish the differential diagnosis between the *cancroid* and the gummy ulcer. Let us add to this sign some other consideration of a less important order—thus:

The *cancroid* is unilateral, azygos, according to the expression of M. Ricord, whilst gummy ulcers are sometimes multiple.

The *cancroid* is more fungous, more bleeding than the gummy ulcer—less grey, less full of shreds, not sharply cut, less emptied out, and more granulating than the gummy ulcer; it secretes a more foetid ichor, and determines more marked local troubles, and especially more pain.

Lastly, a final and excellent differential sign, of which, unfortunately, we cannot always avail ourselves, is the state of the glands. At the commencement there is no glandular enlargement in either of these affections; at a little more advanced period the glands are pretty frequently enlarged in cancer, but remain stationary in the gummy tumour.

Such are the considerations on which the diagnosis of the *cancroid* and gummy tumour may be commenced, without, of course, speaking of commemoratives, or actual syphilitic accidents, &c.—considerations on which I have dilated apropos of the general question as to the tertiary lesions of syphilis, and over which I do not need to return.

Finally, in case of doubt, before deciding to take to the bistoury, there is an evident necessity to have recourse to what has been termed the *therapeutic test*. If there be doubt, and even if the point be not absolutely demonstrated, and that without possible contradiction, the formal indication, which is absolute, is to treat by specifics before operating. To justify this precept, remember the case of Cloquet, the case of Lallemand, to which so many more might be added.

distinctly by the pathological appearances discovered *post mortem*. There is that most widely known when you have septic emboli, and scattered abscesses caused by them, and perhaps otherwise also. There is that where you have inflammation of the peritoneum and other serous cavities, including the synovial and endocardial. There is that where the mucous membranes are chiefly affected—the muco-enteritic. And, lastly, there is that where the only results found after death are—alteration of the blood, enlargement of the spleen, the liver, and degenerations of their most important tissues, with similar degenerations in other organs. It is this last which, often rapidly fatal, was described by Helm, and is now often called acute septicæmia. These are the cases which the superficial pathology of our young days described as having no post-mortem appearances at all. An autopsy in those days was made by any practitioner, occupied only a few minutes, and the observations made were of corresponding value. Now an autopsy is a matter understood to demand the labour for a long time, often for hours or even days, of an expert. On these fruitless autopsies where no appearances were discovered and none supposed to be discoverable, was founded, as you will remember, an argument supposed to be of clenching potency in favour of the essential fever character of the disease. But I confess I have never been able to discover either the logic or the power of the demonstration.

Easily getting rid of this old argument, we come sharply in contact with a new difficulty. When I say that Weber, Bergmann, Billroth, Hüter, and Verneuil support the doctrine, that Olshausen holds it an open question, and that Sanderson, in his essay on the *Infective Product of Inflammation*, demonstrates truths which seem at least to favour its pretensions, you will see that the matter has already occupied great minds. The doctrine is antithetical to the essential fever notion, for it states that pyæmia, or so-called puerperal fever, does not essentially differ from ordinary inflammatory fever, such as is called healthy, except in degree, and that the modes of induction of these feverish states are identical, or nearly so. From the slightest pyrogenous effect or merest evidence of morbidity, as discovered by the thermometer, up to the most rapid of Helm's cases of acute septicæmia, we have one disease in different degrees or forms, all depending on a chemical poison of Schmiedeberg and Panum, or on the bacterium of Mayrhofer, of Lister, of Klebs, of Waldeyer, of Heiberg, and of Orth, whether this bacterium be the poison, or only its carrier. That there are weighty reasons for entertaining this view must be admitted, and among them not the least is the wonderful results of the antiseptic system of treatment, as not only preventing pyæmia, but as preventing ordinary inflammatory fever. But practitioners of my own age, or greater, will find it difficult to get rid of, or convert, the *prima facie* evidence in favour of the old views afforded by the great array of facts and ideas which forms the basis of our daily reasonings in the guidance of practice in healthy and unhealthy inflammations, and which furnish a set of arguments which have been well stated by a reviewer in a late number of our medical quarterly journal.

The disuse of the term puerperal fever, and the replacement of it by puerperal pyæmia, is a change which has already been carried out by many of our best obstetric authors. The old designation is so impregnated with erroneous and misleading theory, that it cannot, within a reasonable time, be purified, and will probably be most advantageously subjected to destructive cremation. Fordyce Barker, a recent American author of great intelligence, still upholds the old banner—"an essential fever peculiar to puerperal women, as much a distinct disease as typhus or typhoid." He well knows how pathologists believe they have torn this view into tatters, and he ought to have given us good evidence of its being reparable, if not actually rehabilitated, but he does not even attempt the difficult task. When we are asked for evidence as to the specific characters of typhus or typhoid, we can easily produce them, and defy the farther destruc-

#### ADDRESS IN OBSTETRIC MEDICINE.

By J. MATTHEWS DUNCAN, M.D.,

Physician to the Royal Maternity Hospital, and Lecturer on Midwifery in the School of Medicine, Edinburgh.

#### PUERPERAL PYÆMIA, ETC.

(Continued from page 157.)

Pyæmia occurs in several forms, which are characterised each by more or less peculiar symptoms, but most

tive analysis of these diseases. It would be a waste of time to go over the special history of the causes, progress, and results of these diseases. They are well known, clear, and convincing to all. For puerperal fever, we have no such characters—no such evidence. All the evidence brings the disease into the closest alliance or identity with surgical pyæmia. The grand modern history of pyæmia is, in fact, at every step of its progress, the history of the elucidation of puerperal pyæmia, or of so-called childbed or puerperal fever.

One error is sure to bring another in its train; and so we have the widely prevalent belief that this disease is like cholera, or small-pox, or typhus, in occurring sporadically, but chiefly epidemically. Here it must be observed that many authors use the word epidemic carelessly, or as synonymous with endemic; a common error which should never be committed. But, knowing this, we find them almost universally believing in real epidemics of puerperal fever, describing them as sweeping over a country or devastating a continent. It is well known, and indeed needs no further proof, that the disease has often the appearance of being endemic in an hospital, that it attaches itself to and follows certain individuals in their practices; but have not been able to find anything worthy of the name of evidence to prove its epidemic prevalence at any time or in any large district. You are all, no doubt, familiar with the long descriptions and marvellous statistical compilations adduced as evidence of this doctrine by our best writers, especially by medical historians, among whom Hirsch is pre-eminent. But when these statistics are subjected to scrutiny, they are all found wanting, as may be made plain by one example, and the examples are all from old times. We have few epidemics described in recent times, and these few do not produce respect for the doctrine implied in their description. Yet, though there are few descriptions now, there is still everywhere the erroneous belief. Epidemics are described as having occurred in Edinburgh in 1772, 1814, 1825, 1833. But it is mere assertion. There is not a tittle of proof that the disease was not as prevalent in every year as in the years of the so-called epidemics. When a physician, struck with awe by a few cases, writes a description of them, down it goes in the statistical tables as an epidemic; and the year of it is not always that of the cases, but sometimes that of the publication of the pamphlet or book. When the horrid mortality rises in an hospital, from overcrowding or other causes, down it goes again as an epidemic; and with this supply of burlesque evidence the manufacture of epidemics never ceases. Registration arrangements are not required to show the epidemic character of cholera, or of small-pox, or of other fevers; and, when we do get the valued registration statistics, we get the proof in proper form. But if puerperal fever is to be shown to be ever epidemic, it must be by regular modern registration statistics. The prevalence of it is happily never very great, comparatively speaking, and, again, it is never extensively or long absent; and, when we appeal to such statistics of metria as are accessible, we do not get proof of epidemic character. We find it always present, in every country, in every community. It is easy to get proof of the epidemic characters of fevers, but not of puerperal fever. He who studies this point will find metria to vary in its ravages as pneumonia does; he will find cholera or scarlatina varying in their ravages according to a quite different law.

As the disease is erroneously believed to be a fever and to occur in epidemics, so we have a corresponding erroneous theory of its origin or causation. Many authors delight to speak of cosmic or of telluric influences or of miasma as producing the disease, and such subjects are favourites with a certain class of minds which find it most agreeable to enter at great length upon those topics of which they know very little or even nothing. For such there should be a puerperal Zadkiel. It is very difficult to find any evidence for the existence of a miasma even in the air of a pestilential hospital, for puerperal pyæmia prevails in such a manner as is scarcely reconcilable with the miasma

hypothesis, and, on the whole, easily reconcilable with more or less direct communication with diseased neighbours, as Veit has ably shown. Among the circumstances of prevalence to which I allude are the comparative immunity of women brought into the hospital already delivered, the special liability of primiparae, the special liability of those who have tedious and difficult labours.

Again, as the disease is believed to be a real or essential fever, so, of course, it is believed to be contagious and infectious, or both—whatever these terms may mean. In recent times, this mode of communication has come to be regarded as so certain and yet so subtle and mysterious that many teachers and a great body of practitioners have been terrified out of their senses by it. One cries out that the obstetrician must not wear gloves, and it would be just as rational to say he must not wear clothes. Perhaps he might be permitted to paint and go about his practice as the ancient Britons fought. Many say that the practitioner who has a case of puerperal fever must give up his practice and go through various processes, and not return to his avocations for a period varying from a fortnight to six weeks. Others, on this point speaking logically, go further, and say the accoucheur should give up his practice, not only if he has on hand a case of puerperal, but of many other contagious diseases, such as scarlet fever, typhus, small-pox, measles, erysipelas, fœtid abscesses, &c. Of the many who propound or teach such doctrines, I have never known one who practised them, and I cannot say their feelings on reflection are to be envied. If such are good doctrines, they are, of course, equally good for physicians and surgeons as for obstetricians, but the poor obstetrician is laden with restrictive burdens which his medical and surgical brethren do not recognise or touch with one of their fingers. Yet, the old proverb tells here, that what is sauce for the goose is sauce for the gander, and accordingly physicians and surgeons must follow the rules they inculcate on the accoucheur. In truth, these extreme practical doctrines of contagion are absurd, for they render all practice, whether medical, surgical, or obstetrical, an impossibility, or at least reduce the number of patients cared for at a time to one, which amounts to the same thing. In this matter much error and evil are, I believe, introduced by confusing the duties of the practitioner with those of the nurse, two quite different and almost, if not altogether, incompatible occupations. A practitioner must always, in such circumstances as we are now considering, carefully eschew undertaking the functions of a nurse, for if he does, he must submit himself to the code of rules that regulates the conduct of nurses. If, avoiding a nurse's duty, a medical man of any kind cannot make himself medically clean in hands and person and dress, all kinds of medical practice as at present carried on are impossible with due regard to the safety of patients. Everyone who knows the safety of actual medical practice must see that such views of contagion end in absurdity. But it is not, despite all this, to be supposed that practitioners are not bound by the most solemn considerations to take most scrupulous care against being disseminators of disease; and there is no disease with which they deal where such care is more imperative on them than puerperal pyæmia. The puerperal woman presents in her contused, lacerated, and inevitably wounded passage the most favourable nidus for the reception of morbid material; and the woman suffering from puerperal pyæmia in any of its forms, and patients suffering from some of the allied diseases, present this morbid material in its subtlest and most potent essence. A well-demonstrated communicability arises from this source. No other has been demonstrated, but it is possible that in an ill managed hospital there may be some other. For the existence of another source, several of the best recent authors offer slight evidence; but, on the other hand, its existence is rendered very doubtful by the alleged absence of pyæmia in those surgical hospitals or parts of hospitals where the antiseptic treatment of Lister is properly carried out.

Another result of this extravagant and superstitious

dread of contagion is what I deliberately call the slandering of our noblest and most useful institutions—hospitals—and in that word I include all hospitals for the sick, not those for lying-in women only. Although it is against the latter that most of the foolish talk is directed, it is vain to suppose that they alone suffer. If one kind of infirmary is indefensible, so are all kinds; they must stand or fall together. The laws of pathology are not varied in nature with a view to the misfortunes specially of lying-in women. No doubt the slandering is done with an excellent intention, under a good motive, but it is none the less what it is called, censuring injuriously and falsely, or without sufficient evidence. There have been, and there may be now, maternities which are justly calumniated as injurious, but that fact is no excuse for calumniating all. After abundant evidence has been adduced to show the directly and indirectly erroneous character of Le Fort's statement, that while the mortality of hospitals is 1 in 29, that in private practice is 1 in 212, a recent lecturer on pyæmia repeats it as if it were uncontested, and weakly appeals to authority on a point capable of scientific demonstration. We have reliable and large statistics to show what a moderately good hospital is, and we have no thoroughly reliable evidence that better results are anywhere obtained, whether within an hospital or in private practice. Among the good, I place the Rotunda of Dublin, the reports of whose recent condition you may have seen from the pen of Dr. George Johnston, its present master. So great is this superstitious dread of hospitals and reliance on imperfect statistics, that one eminent author believes he has made out that amputation of the forearm performed upon a poor man in his cottage is thirty times less fatal than if it were performed in an hospital. The paradox is not to be received because its basis is inadequate; and, considering whence come most of our hospital patients, I wish we had from this author some theory of the healing virtues of the concentrated and various filth of a highland bothy or cottage, or of a den in the Edinburgh Cowgate, or the London Ratcliffe Highway, accompanied, as it often is, by every abomination physical and moral.

As hospitals are in this facile manner made out to be bad, so of course, large hospitals are worse, and statistics are again appealed to in support of this view. Were it not that a recent lecturer on pyæmia repeats this statement, I would not here allude to it, for it has been shown to be groundless by demonstrations as good as can well be imagined, but which seem not to have reached the eyes or mind of this eminent surgeon. Siebold believed that lying-in hospitals were so useful that shutting them up would bring far more serious evils than an occasional outbreak of puerperal fever. Whatever soundness there may be in Siebold's judgment, I prefer, with Steele, to adopt a different view of maternities, and to look forward to the time when there will be no endemics of puerperal pyæmia, but only sporadic, or what are called auto-genetic cases.

Other errors connected with the old and still prevalent opinions regarding puerperal fever, though worthy of comment, must be passed over; but one, from its importance, demands notice. It is, that this disease is a kind of cholera, or a kind of typhus, or a kind of scarlatina, or owns the same or similar causes. In this country it is almost exclusively the identity with scarlatina that has found supporters. But at home and abroad the doctrine has, in some form or other, been extensively entertained. It is to be carefully distinguished from that reasonable view of Pouteau, Alison, Sidney, Nunneley, and Tilbury Fox, that the disease has close alliance with erysipelas, and, I might add, with the diffuse information of Duncan, a view which has been partially adopted and signally illustrated by Virchow in his now celebrated paper on "Diffuse Puerperal Parametritis." Scarlatina is a source of terrible danger to lying-in women, and scarlatinoid rashes are seen in some of the worst cases of septicæmia; and herein probably lies the attractiveness of the theory. But, unluckily for its supporters, and especially for the

most recent, the theory has been disposed of by the researches of Hirsch and of Veit, who, by statistics of the comparative prevalence of scarlatina and of puerperal fever at different times and at the same time, have shown that there is no relation between the two. This argument against the theory is far stronger than any in favour of it, and must meantime be held as conclusive. It had been urged by these authors and by Spæth before the *Lancet* did the good service of bringing Farr into the field on the same side.

Every change in doctrine or in name does not necessarily indicate progress; often, indeed, it indicates retrogress. Such unfortunate changes arise more frequently from error in philosophising than from error in observing. Among such, there is one in the history of our present subject. It has by some pathologists been proposed, not only to continue the name puerperal fever with all its adherent errors, but to go far towards introducing like errors into surgery by describing the allied diseases there as surgical fever. Had there not been the erroneous use of the word fever in childbed diseases, there would undoubtedly have been one hindrance less of the general acceptance of modern views. Progress in surgical pathology runs no risk of being now impeded by the false name, surgical fever; and its adoption will certainly not do any good. By adopting, instead of puerperal or childbed fever, the term puerperal pyæmia or some similar one, we, by the mere use of words, enforce the argument for a great medical generalisation, making the gains of surgical and obstetrical science mutually beneficial.

It must not be supposed that there is in the mere change of a name any real progress, however much such change may foster right views. Nor is this change of name to be held as even tantamount to a change of theory, from a false to a true one. The present state of our knowledge is not such as to justify a sense of great security in any theory. Yet, theories are very attractive, may be useful, and the tendency to frame them, whether prematurely or not, is in vain repressed. All the more ought we to maintain our minds in an unprejudiced attitude, ready to throw away the worse and cling to the better. Willis, who introduced the name febris puerperarum two hundred years ago, held that it was the result of sulphurous particles and fermentation. This has a faint resemblance to the new pyæmic theory, with its bacteria or micrococci, its septic and infective materials; but Willis's theory and every recent modification of it is a mere shadow compared with the pyæmic theory. The former can scarcely be said to explain or embrace any of the chief details of the subject, while the latter explains and embraces a vast number, is incompatible with none, and is the most promising road to still further explanation and generalisation. It is the last philosophic production of a vast array of modern observations and inquiries. It helps to increase the distance between us and the mere philosophisers, and to join us with the advanced guard of modern medical investigators, whose weapons are observation and experiment, not learned talk, however clever. When the physicist finds a theory of light propounded by the greatest of his kind to be inconsistent with his more advanced researches, he not only adopts a new one, but deserts the old nomenclature connected with the misleading hypothesis.

Many researches of different kinds have contributed, and are contributing, to converge scientific light on this greatest of practical, obstetrical subject; but scarcely one of them can be regarded as being even yet completed, while some are only well begun. In drawing to a conclusion, it will be well to take a glance at these various investigations, with which we may class some more general discussions, such as that of Spiegelberg, on this topic.

Van Swieten, Willis, and many old authors on puerperal fever, regarded it as a wound fever, and Eisenmann's well-known work on the subject, published in 1837, is called "Wound Fever and Childbed Fever." The wound which these, and even most recent authors, have in view,

is that produced by the separation of the placenta; but it is now well known, and has been often found clinically exemplified, that the disease may begin in a contusion or laceration of any part of the genital canal. Many of you have recognised the beginning of a fatal disease in a diphtheritic state of a slight recent perineal laceration, with surrounding redness and boggy swelling. I have already alluded to the recent advances of our knowledge of the anatomy of the placental wound, but already we know where to look for much more light on this subject. The anatomy of the lymphatics, to which recently Recklinghausen, Klein, Thin, and many others, have contributed, is not yet completed for the uterus. We all know the fine-looking and distinct, but very unsatisfactory drawings of uterine lymphatics by Moreau; but we do not yet really know their actual anatomy, though very much progress has been made by the anatomical investigations of Lindgren, Fridolin, and especially of Leopold. The completion of this work will be an addition to the theory of puerperal pyæmia.

Following the as yet indefinite notions of a wound-fever, came a further true advance from Boyer, Legallois, Cruveilhier, Tonellé, Dugés, and Simpson, who combined to demonstrate the identity of what would now be called the rough morbid anatomy of patients dying after surgical and after obstetrical wounds.

Then came a grand piece of progress, consisting in the discovery and descriptions of phlebitis and lymphangitis, which we owe to Dance, Duplay, Cruveilhier, Robert Lee, Hecker, and Buhl.

We now reach our own times, and have a still grander progress of our knowledge to record, in the discovery of thrombosis and embolism by Virchow, Kirkes, Cohnheim, Buhl, and many others.

After these come researches whose bearings on this subject are certainly very important, but which are, in many respects, as yet immature and incomplete. We allude to the investigations as to the potency of septic poisons, connected with the names of Davaine, Panum, Kehrer, Thin, and many others; the great and actively progressing researches as to the production, diffusion, and influence of bacteria of various kinds, by Lister, Klebs, Waldeyer, Sanderson, Billroth, Winge, Heiberg, Orth, and many others; the new researches of Sanderson on the infective product of all acute suppurative inflammations; researches also into the distinctive characters of the noxious or septic, and the innocuous bacteria.

Besides all these, many valuable results have been elicited from the analysis of experience in hospital and in private practice. In this way the influence of age has been ascertained, and especially of immaturity and of advanced life; so also the baneful influence of primiparity and of excessive childbearing, and of twin-bearing; so also the baneful influence of severe and of complicated labour; so also the bearings of the duration of labour; so also the influence of earliness or lateness of attack after delivery; so also the baneful influence of inclemency of season; so also the dangers attending hospitals and the dangers of communications between the sick and the healthy.

But all of these researches, whether finished or still imperfect, do not, when combined, complete our modern view of this great subject. It is a subject in practical medicine, and we are practitioners. The great object of our work is to prevent or to remove the disease in our patients, and we have to inquire what fruits our knowledge produces for the comfort or healing of the sick.

Many remedies for puerperal pyæmia have been proposed, and their successful application loudly proclaimed and widely believed. Doucet was even rewarded by the French Government for his discovery of the curability of this disease by ipecacuanha. In our own day new cures do not fail to make their appearance, and the advanced knowledge of our times would lead us to expect that they should be more rational, as the phrase is. But who is there of weight in the profession, now, who believes in any cure or in any system of specific treatment? All have

been found wanting. Yet the wise physician of this formidable disease does not despair of guiding his patient through it, although he well knows its very dangerous character. Experience has shown him the utility of several means for relieving sufferings; and the favourable progress of a case may be encouraged, though not secured, by those invaluable directions which he may give as to diet and stimulants, as well as to more direct medicinal treatment of the genital passage, of the skin, of the bowels, and of the system generally.

But in this disease the physician has long been saying, not that prevention is better than cure, but that prophylaxis or prevention is to be chiefly looked after, and not cure. Great credit is due to Semmelweis for the good he has done, especially to hospital patients, by his enlightened zeal in this cause; but the records of hospital practice sufficiently show that much more has yet to be accomplished. Prophylaxis is still farther to be carried out by attention to stop injurious communication between the sick and healthy, by disinfection, and by architectural arrangement—subjects which are all at present receiving much attention from the profession.

In the course of my remarks I have repeatedly referred to scientific researches, as to the poison producing pyæmia, and as to the effects of its concentration, and as to the connection of this poison with the presence and diffusion of bacteria. These researches have been carried on mostly by observations and experiments on the lower animals, and of their very great value there can be but one opinion. But there is a variety of circumstances which seem to indicate that the lower animals are not subject to exactly the same laws in these matters as man is, and certainly there must be great caution exercised in arguing in human pathology from the analogy of the lower animals. The most important of the researches referred to, however,—those of Lister and his followers—have been mainly carried out in man, and consist, in a great degree, in the attainment of results in practice equally wonderful and valuable—results that can, so far as we at present know, be attained in no other way. These results go far to justify the belief that pyæmia is a septic disease, and that puerperal pyæmia may be almost, if not altogether, prevented by the application to delivery of a practice based on antiseptic principles. We know how much has already been, and is, I am happy to say, daily done with success in this direction. But the rules of Semmelweis, or any other washing of the hands, however carefully conducted, do not constitute treatment according to the manner of Lister. Such imperfect antiseptic precautions, by use of antiseptic gauze and otherwise, I have used with apparent advantage; but we have yet a long way to go, in order to secure complete antiseptic delivery and subsequent treatment. To reach this desirable object, the efforts of several good minds are, I know, directed both at home and abroad; and some recent unpublished cases of successful antiseptic treatment of wounds of the penis, where periodical discharges of urine have to be permitted, supply a sketch in miniature of plans that might be applied to ordinary confinements. To say more about them I have no right; but I conclude by calling upon you to give your best aid to forward the grand cause of the increased safety of lying-in women.

## MEDICAL SCIENCE AND MEDICAL TEACHING.

By GEORGE BARRACLOUGH, M.A. (Cantab.), M.R.C.S.

(Continued from page 131.)

If it be true that in the scientific works of a great physicist like Faraday not much of the personal processes of thought by which he arrived at his discoveries is manifested, it is fortunate for us that the history of these processes has been preserved for us elsewhere. A recollection occurs to me of having seen a letter of Faraday's in which he himself describes spontaneously the intellectual processes by which

he arrived at his discoveries. I cannot lay my hand on this letter at the present moment; but in illustration of the subject, I find something in Tyndall's "Faraday as a Discoverer" quite as much to the purpose. The narrative runs thus: "Theoretic ideas were the very sap of his intellect—the source from which all his strength as an experimenter was derived. While once sauntering with him through the Crystal Palace, at Sydenham, I asked him what directed his attention to the magnetization of light. It was his theoretic notions. He had certain views regarding the unity and convertibility of natural forces; certain ideas regarding the vibrations of light and their relations to the lines of magnetic force; these views and ideas drove him to investigation. And so it must always be: the great experimentalist must ever be the habitual theorist, whether or not he gives to his theories formal enunciation. . . . Faraday himself, in fact, was always 'guessing by hypothesis,' and making theoretic divination the stepping stone to his experimental results." (Tyndall's "Life," pp. 97 and 149). Dr. Wilks is not very fortunate in his choice of Faraday as an example in support of his doctrines. It is quite clear, if the above citation is to be trusted, that the methods which Faraday adopted in his researches were the very antithesis of those which Dr. Wilks deems "truly scientific." Faraday, indeed, made all his discoveries by those theoretical methods and that sort of personality of thought which are impugned by Dr. Wilks. Had not Faraday, consciously or unconsciously, pursued such methods, it is quite certain we should have heard neither of him nor of his discoveries. What a loss it would have been to us had not Faraday either directly or indirectly revealed the personal mechanism of thought, in the formation of theory, which led up to his discoveries, and of which these were merely the result, or final expression. If the revelation of this had not been preserved for us in the way it has, rather than not to have had it at all, would it not have been to our advantage if Faraday had mingled the personal mechanism of thought which led up to his discoveries, with the formal enunciation of them? And would his scientific doctrines have been less true on account of the fuller view of his personality thus afforded us? According to Dr. Wilks, this would have been the case.

Historically, it is simply incorrect to affirm that "all truly scientific theories are completely dissociated from the mind of him who has framed them." Whether they can be so dissociated is one thing; whether they are (*i.e.*, have been) so dissociated in all instances, is a question of history; and history testifies to no such thing. So far as the mere power of complete dissociation goes, if it exists, it holds equally true, as a matter of form, for false as for true theory. If true theory can be *completely* dissociated from personality, there is nothing to show that the same cannot happen with untrue theory. Such being the case, where is the value of this doctrine as a criterion of what is "truly scientific?" Are we, for instance, to accept as true all the doctrines in Plato's dialogues because Plato himself so seldom appears directly in them; or all the conclusions in the treatises of Spinoza because—though still *his*—he invested his thoughts, so far as possible, with an eminently mathematical and impersonal form? Actuated by this principle, we shall find ourselves embracing the most heterogeneous doctrines.

All forms or scientific principles are, in their expression, nothing more than the external signs or symbols of that growth of thought or evolution of soul which constitutes knowledge in the individual mind. Simply in their formal expressions they are lifeless—are not knowledge—are a mere form of words. And hence they are not most fruitful, *i.e.*, most productive of that growth in the minds of men which constitutes knowledge, when, in the language of Bacon, they are exhibited with some of the earth about them. It is this latter process which gives us that helpful glimpse which is such a precious aid towards the evolution, in our own minds or personalities, of the knowledge or sciential soul-growth, of which principles, as expressed in words, are the mere external symbols. Without this aid

the bare enunciation of a principle would indeed be of little use to us unless we were ourselves already largely pregnant with the subject; and according to the degree of pregnancy do we require more or less of the earth. I say, in default of such assistance as this, we might, in some cases, beat about the ground for ever, without arriving at that knowledge of which the principle, as nakedly stated, is the hieroglyph. And this really is precisely the state of the ignorant in respect to principles. To such persons they are wholly inert and meaningless. A principle as nakedly stated in words has nothing inherent in itself by which it can convey knowledge to the unaided or unpregnant mind. The higher the law and the more abstruse the principle, the more numerous must be the intellectual processes which have preceded them, in the case of every individual mind which strives to apprehend them. There is no royal road to knowledge, even by way of principle. In one aspect of it, the growth of knowledge may be described as the advance towards a higher sciential selfhood. And as we cannot transcend personality, all human knowledge must be personal, not impersonal. We may make the formal or abstract principle, as symbolised by vocal or written signs, as impersonal as art will allow; but if this is to be vivified or made into real knowledge, it can only be done by unfolding those intellectual processes which constitute the knowledge of which the mere formal or verbal enunciation is the expression; and only by a metaphor can knowledge be said to reside in this latter. As regards knowledge, the possible fruitfulness of a principle resides not in it, but in ourselves. Otherwise, the bare enunciation of the most abstruse principle would convey as much knowledge, at first hearing, to the perfectly ignorant, as to the instructed, which we know is not the case. "'Tis the taught already that profit by teaching." And we know how Socrates described himself as a midwife. In face of the uncertain result which attends so many of the Platonic discussions, we must not suppose that the Platonic dialogue proposed doubt, or mere skepsis as an end. This was only a means to an end; and that end was the exercising of the mind not only of the *idola specūs*, but of all other phantoms, a getting rid of what was *ιδωρικόν* (in its lower sense), a purging of the mind of the wrong sort of egotism or personality, and a preparation of it for the higher sort; the gradual infusion of a reverential sense of the difficulty and infinite subtlety manifested in the works of the Demiurgus. In this way the ground was effectually cleared of the rankest weed—the conceit of knowledge without the reality. The mind thus ceasing to be merely lay, was in the state to become cleric or sciential in respect to all knowledges—was in a position to evolve knowledge according to the measure of its individual capacity, or develop the highest sciential selfhood of which it might be capable. This was the regeneration, or second birth, the palingenesis which enabled the subject of it to live in the world of reality as contrasted with the phantom world of *idola* or idolatry. And here also that may be affirmed which was said in another and more solemn reference: No man, unless he be born again, can enter into the kingdom of science. "Je mourrai seul" was a saying of Pascal's: he might have added, "We must live alone." No mere contemplation of the exploits of Milo will make our own muscles grow. If growth is what we want, there is only one way to obtain it: we must strip and go into the arena—not standing by and refusing to grip—not fearing a fall, nor that swinging hype which we are sure to get. The kingdom of knowledge suffers violence, and in respect to it we must all be agonistæ. This is true of all worlds, whether physical, intellectual, or spiritual. Let us not, then, give ourselves the airs of grown-up athletes when we are only children playing with the hem of our mother's garment.

As with his conceptions of nature and disease, so it is evident that, in the paragraph I am criticising, Dr. Wilks falls into his error respecting the impersonality of knowledge by conceiving of knowledge as an externally absolute and objective entity, independent both of man and of the Demiurgus. Viewed in relation to perfectly absolut

knowledge, as inferred of the Demiurgus, our knowledge, of course, is relative in reference to this. Apart from this reference, our knowledge is unrelative, and has, so to say, a sort of imperfect absoluteness. But, then, to objectively realise this last conception of knowledge, and represent actual human knowledge as relative to it, is merely to set up an eidolon or phantom which can only lead to that confusion which I have criticised all along. Discontent with the personality of human knowledge has led many, as in the East, to take refuge in the doctrine of Absorption, and not a few—as in Germany—to flee to a kindred doctrine—viz., the Intuition of the Absolute. But such minds have always been profound enough to see the folly of such an eidolon as absolute knowledge independent both of man and the Demiurgus. It appears to be reserved chiefly for the positivist to embrace this phantom; and, yet, considering the hue and cry raised against metaphysical ideas, this is very remarkable indeed. Surely the positivist's creed should, like Cæsar's wife, be above suspicion.

When he writes, "I believe this to be a true canon of criticism," &c., it appears to escape Dr. Wilks' notice that he is "intimately associating himself with his theory." Is his theory, for that reason, to be rejected? or is it to be rejected, independently of any association, solely if found to evince wrong thought, wrong reason?

As the abuse of theory has led Dr. Wilks to a most unphilosophical depreciation of its use as an instrument of scientific progress, so (in theory at least) his just abhorrence of an egotism, vain, obtrusive, and shallow, has led him to erect into a canon of criticism what, in the unqualified manner he has expressed it, is absolutely false and untenable, and, besides, is contradicted by the whole history of the origin and progress of science.

## A Course of Lectures

ON THE

### NATURE AND TREATMENT OF DEFORMITIES OF THE HUMAN BODY,

DELIVERED IN THE MEATH HOSPITAL, DUBLIN, BY  
LAMBERT H. ORMSBY,

Surgeon to the Hospital, and Demonstrator in the School of Surgery,  
Royal College of Surgeons in Ireland.

LECTURE V. (continued from page 397).

#### DEFORMITIES IN THE JOINTS OF THE LOWER EXTREMITIES.

##### *Chronic Rheumatic Arthritis of Hip-joint.*

THIS is a disease that produces at times great deformity in this joint. It has, as is well known, been first accurately described by two Irish surgeons, Mr. Robert Adams, of Dublin, and by the late Professor R. W. Smith; it was formerly called chronic rheumatism of the hip-joint, then morbus coxæ senilis; but the first-named seems to be the generally accepted term in the present day to denote this peculiar disease. Mr. Adams says, as to the cause of this chronic disease of the hip-joint he believes little is known. We have heard it frequently attributed to the effects of cold and wet, and an acute attack of rheumatic arthritis of the hip-joint produced by cold we can easily conceive may occasionally merge into the chronic affection we wish to describe. We have also reason to think that falls upon the greater trochanter have given rise to the first symptoms of this disease, but in many cases no satisfactory cause can be assigned by the patient for the origin of the affection.

*Symptoms.*—It generally occurs in those advanced in life, over 50, but may arise sooner—between the ages of 50 and 70, the most common. I have seen it more in men. One hip or both may be affected, also other joints in the body. It commences by the patient complaining of great stiffness in the joint, and about the greater tro-

chanter a dull boring pain is felt, extending down the front of thigh to knee; the stiffness is most felt in the morning; if the patient has walked much in the day the stiffness and pain are severe in the evening; there is a limitation in the range of motion, pain is felt when the patient places full weight on the affected joint, but when the surgeon presses the head of the bone up against the acetabulum no appreciable pain is experienced, the limb is shortened for about two or three inches, which varies in different subjects, but it is more apparent than real, owing to the obliquity of the pelvis, the nates is flat on the affected side, and the muscle appears wasted. When the joint is rotated, crepitus, owing to the grating, can be heard occasionally. A patient so suffering finds a great difficulty, in fact, in some cases it is impossible, to bend so much as to touch their toes; the attitude of standing and mode of locomotion are quite characteristic—they stand on the sound leg, slightly bent forwards in body, and rather spread the affected limb out, and with a slight bend at the knee, and the mode of locomotion is generally by the aid of two sticks, and is accomplished very slowly and interruptedly, the body slightly bent forwards at the hip. The anatomical or pathological appearance in the joint is as follows: The muscles are flabby and atrophied, the capsule is thickened, the synovial fluid is deficient, and if any of the sub-synovial tissue is present, it is very red and vascular, the cartilage of incrustation is removed from the bottom of the acetabulum and head of the bone, exhibiting at times a polished porcelaneous appearance, due to friction of the two bones against each other; the cotyloid ligament is frequently ossified; the acetabulum is deeper and larger, and forms a deeper cup than usual, with a level brim round the head of the bone, and narrowed so as to make it difficult to remove the head of the bone when required for examination after death; the Haversian gland is completely removed; the ligamentum teres is either ossified or entirely destroyed; the head of the femur is rounded, or depression, or bony ridges or nodules are seen on its surface; the neck is shortened. Cases of this disease have before now been mistaken for osseous tumour in intra-capsular fracture; these little bony deposits may be developed round the acetabulum and capsular ligament. I merely mention this disease on account of the deformity, in order that you might be aware of it and not mistake it for anything else. As regards the treatment it is at its best state but palliative; as yet no remedies are suggested for the purpose of curing it permanently, being a disease of advanced life and one of disorganisation and degeneration of the several tissues constituting the joint.

#### APPLICATION OF AUTOPLASTY BY THE FLAP METHOD FOR THE CURE OF SALIVARY FISTULA.

By J. MORGAN, F.R.C.S.I.,

Surgeon to Mercer's Hospital, Dublin, &c.

THE various modes of treatment suggested for this troublesome affection bespeak the difficulty which has been experienced in obtaining its cure; the affection is in itself so annoying and unpleasant, apart from the physiological loss to the animal economy of a secretion which is poured forth and lost in such quantity, that extreme measures have been resorted to so as to obtain a cure on any condition, even at the expense of the destruction of the gland itself. The actual and other cauteries, the seton, the refreshing and paring of the opening, the application of a suitable canula, and various other means have been used with varying success, and not unfrequently with vexation and disappointment both to patient and surgeon. I have found the flap autoplasmic method most successful, as illustrated by the following case:—

A child, 3 years of age, had suffered from abscess of cheek, followed by fistula of the parotid, just as the duct emerges from it. The opening was about the size of a

very large pin-hole, with puckered edges; the quantity of secretion poured out at times was incredible, and saturated the child's clothes, giving constant annoyance. The patient had become irritable and pallid, and suffering evidently from imperfect nutrition.

For some time I tried with perseverance the application of collodion, pressure, caustics, paring the edges and coapting them, but with imperfect results. I finally adopted the treatment by flap, as in the accompanying woodcut. A flap of skin was raised up from immediately

above the fistula, the parts below and in its vicinity being also denuded. I then drew down the flap over the fistula, and attached it by points of fine suture, and coated the whole over with flexible collodion, which was renewed from day to day when required. The result was most satisfactory. After eight days the collodion was discontinued, and a perfect cure was effected. The child's condition improved incredibly in a very few weeks. I applied a similar flap method in another case, with equally happy termination, and can fully recommend the method as applicable and successful.

## THE PHILOSOPHY OF VOICE.

By CHARLES LUNN.

(Continued from page 532.)

THERE only remains to be shown the best mode of self-study, and the influence of second causes upon pitch, so that the student may know what differences in hue to accept as true and what to reject as false; this because compass is as much a means of oratorical effect as it is of song. The best starting point for study is the note produced by sole approximation of cords, wind and reed synchronising, for in this the conditions both of elevation and depression of pitch are not involved; the note produced from the detached larynx by imitating the action of the adductor muscle would give the easiest sound in the living subject; this, in the average adult, male or female, is middle G, and in strange corroboration, we find G accepted long ago by priests as the most convenient note upon which to recite words. Having fixed the station note of equally sustained tone and of unflagging strength, all notes below are made by the larynx sinking and the attendant relaxation of the cords, from the detached larynx, male and female; Dr. Wyllie produced an octave below the station note; a like octave can be produced from the living subject. For the notes above G the larynx rises, and in rising causes increased tension of cords and a correspondent elevation of pitch. In this ascent the thyroid and cricoid rotate upon an eccentric centre, causing the planes of both false and true cords to become with each heightened tone more diagonal, thus, the sound travelling at a right angle to these planes finds its points of impact on the arch of the palate more and more forward with each ascending sound. A change in hue arising solely from change of direction has been a great source of error in our teachers, who, when speaking of "registers," have invariably been misled by this. The

object Nature evidently has in directing tone is that with equally developed force vocal utterance and articulate speech can be simultaneously used without one influencing for evil the other. This affords another scientific proof of the superiority of the fast dying old school which insisted upon a "forward production" as a basis for song. The reason why the larynx does not assume its right elevation for higher notes than the station note is because during our past years it has only been used *indirectly* to strengthen spoken words, so that the tendency of the larynx is to assume and retain the average altitude of language and to leave the production of all notes of greater height to volitional force acting through the thoracic muscles alone. Most untaught persons produce sounds above the station note by excess of blast, as seen by the rapid exhaustion of air, as heard by the point of impact being far back in the mouth, and as felt by the larynx being low, and finally corroborated by a feeling of personal fatigue when such notes are given forth. The corrective study is not, as alleged by Madame Seiler, "uttering *ah* in connection with consonants coming rapidly, as in *pfa, bfa*," for, as before remarked, a noise generated elsewhere cannot assist the organ of voice in directing its own tones, but the corrective study is, as the truer teaching of Garcia shows, having recourse to a steady spring from the larynx; this, by practice, induces in it a habit of rising until a position of highest elevation is fixed. It may be added, experience of years of voice-training shows that about C is found the best place for fixing the first central tone, and from this working downward to G inclusive. A curious phenomenon occurs about D or E: if the larynx ascends above this point the sound is propelled directly out of the mouth without any reflection on the arch—thus, a shout or noise results; doubtless this is the production spoken of by Dr. Mackenzie as of "too high a pitch." This, then, is the natural law; as soon as the sound obtains no reflection the scale must be continued by letting the larynx *sink* and going over the preceding five notes, G to D, with greater pressure, thus elevating them a fifth (full harmonics.) The descent of the larynx about high E can be felt with the finger; all these notes above D are producible in more ways than one, but all depend upon a correct emission of the tones below, so that the old teachers were right in insisting on fixing middle and low notes, although they did not know the reason why this should be done. In *soprani sfogati*, *tenori robusti*, and in all low voices of either sex, the notes above D are full harmonics produced by increased blast acting upon the cords fixed for a fifth below; but in "light" voices the notes above D are harmonics on a "node" from the cords fixed for an octave and sometimes for a twelfth below. By emitting a deadened high note (*falsetto*) and pressing above the thyroid with finger and thumb the sound will suddenly burst out into a bright clear tone; this is the production sought for by light singers. In the living subject there are three series of tones: one set produced by relaxation, one set by tension, one by reproduction; and the physical facts producing these three series are made manifest to man through created sound by three entirely natural but different hues. We know that air confined in spaces will strengthen and re-enforce sound (Mr. Sully in his admirable essays calls this "co-vibration"); in a human body there are three caverns filled with air that influence tone—the chest, the pharynx, and the mouth—and that cavern which of the three exercises the preponderating influence in tinging tone has hitherto been used to give a name to that series of sounds so tinged; thus we have one set of sounds termed "chest," and another "head." Moreover, with an increasing current of air from below, so sound will be carried by the current in one direction and impeded in a contrary one. Now, as all these second causes are absent during observations on the detached larynx, and as all remarks in medical works are drawn from this aspect of observance, we naturally find men of science writing of the "register" of voice (2 octaves),

while musicians approaching from a different point have confusedly brought in all second causes, and so speak of the "registers" of voice; hence the discrepancy in the statements of the two classes of men. The sudden change of hue in the female voice between middle F and G takes place just the same in the male voice, an octave lower, but owing to the difference in thoracic form the resonance continues in the chest of man where it ceases in that of woman; the ignorance of this physical fact is the cause of much false teaching, and has entirely blinded all previous writers.

It will be well here to clear away a false statement of the physiological action which takes place in producing "chest" notes. Herr Behnke, as reported by the *Lancet*, said at King's College: "The chest voice, which is the lowest, was said to consist of two portions, the lower and the upper. In singing in the lower register, the vocal cords are approximated for nearly the whole of their extent, but a small aperture remains between the arytenoid cartilages, and by the passage of air between them the cords are thrown into a full loose vibration." But Dr. Prosser James, in his articles on "Diseases of the Throat," (a) reproduced some observations on lost voice which strangely conflict with the foregoing; speaking of the patient, the article continues: "This (i.e., loss of voice) was at once explained by the laryngoscopic examination, which showed that there was not the slightest approximation of the vocal cords on attempting to speak, and the glottis remaining widely open, a large volume of air was required to be forced through it in order to produce even the faint whisper above mentioned. This demanded an effort of the expiratory muscles which was very fatiguing. The larynx appeared in every way healthy." And further on it stated that after an application of electricity "the voice had become very much louder, so that it could be heard the length of a large room, and the patient no longer complained of fatigue even after a long conversation. But at this point the improvement rested. On attempting phonation there still remained a *triangular opening in the glottis posteriorly, showing that the arytenoides failed to act.*" (The italics are mine.)

Here we see that what Herr Behnke advocated as a natural law Dr. Prosser James advanced to prove paralysis.

Further, it is assumed by voice-trainers that because there is a difference of hue between one series of sounds and another series of sounds that Nature causes a "break" in the voice, which break has to be "bridged over" (see any vocal tutor). But a difference does not necessarily involve a defect; therefore what is ignorantly termed a "break" may with better judgment be termed a "joint." A break is a bungle of ignorance, and the use of the term by the profession is giving to airy nothings a local habitation and a name to deceive the public and allure the unwary; the term itself is based on the assumption that Nature habitually creates man a cripple, and thus teachers complacently proceed to destroy a natural diversity in hue under a pretext of covering an imaginary gap. The hue with which each register is coloured, and which men try to annihilate, is given by Nature for a definite purpose, and is entirely right. This brings us to the science of aesthetics, which science is broadly divisible into that which stimulates, which may be called motion, and that which depresses, and which may be called repose. Power will excite, softness will tranquillise; so with height, and the opposite, depth; and with quickness, and its opposite, slowness.

<i>Motion.</i>	<i>Repose.</i>
Power.	Softness.
Height.	Depth.
Quickness.	Slowness.

(a) MEDICAL PRESS AND CIRCULAR.

The contradictories of any one of the above terms are found in the correlatives to the accompanying other two; thus, the stimulus derived from height can be counterbalanced by slowness and softness; but in the voice, wherever we require an outer manifestation of constant excitement, Nature has strengthened her æsthetic law by fixing a hue which expresses that mental state irrespective of the words associated therewith; and wherever we require an outer manifestation of constant repose Nature in like manner has fixed a corresponding hue. These are immutable results arising from an affinity between the receptive faculty and the intrinsic properties of the instrument. But where all kinds of expression are shown, that is, in the ordinary colloquial compass, the tone is a negative one. (a)

Voice-training was originally the work of past great singers, who taught by imitation; of late years this work has been added as an inferior adjunct to teaching the piano, the result being that we occasionally get a half-taught singer, who is carefully exhibited at great cost on festive occasions, and caused to sing to us, while we for the most part remain a nation of dumb mutes; thus, the public have got to look upon a beautiful voice as a freak of Nature, or a beautiful monstrosity, instead of being, as it is, a common gift of God to all, implanted in each of us for solace in sorrow, enjoyment in leisure, and spur in work. The difference, then, between the present articles and the faultful suppositions propagated in accepted vocal works is this: each of the existing works is started on the premiss that the writer is great and Nature poor and small, while these papers assume man's littleness and Nature's greatness, and assert that men are better employed in perceiving a true thing than they are in conceiving a false one: to this end the economy of Nature has been shown, the gradual decline of tone through lost relativity has been traced, together with the introduction of spurious vicarious force, and the association of nerve-currents by use of spoken words. The modes of restoration and re-adjustment by decomposition of nerve-currents and the severance of vocal tone from articulate speech have been pointed out, going back in all simplicity to first principles as shown in child-life; and, finally, the gradual development by steady right directed work has been enforced. We have seen how conflicting opinions have arisen, and how these and observations from different aspects can be explained, and, where each in its way correct, made to agree, and we have seen how science has been retarded by voice culture having got into the hands of a wrong set of men. Of course, a true teacher of music would see the immense advantage that must accrue to his profession if voice-trainers had a separate sphere of action, and could hand over their work, saying, "Here you have a perfect voice, implicitly obedient to the will of the possessor; it is developed to its uttermost, and refined to the greatest extent that work, aided by science, can attain. Now teach the possessor of such voice to use it with the consummate skill that you, as musician, know best how to impart, then we may by our friendly association of work, and in due time, produce a real artist—not a singer of the modern bastard school." But, instead of that, it is generally assumed that the most difficult branch of all musical training—that of guiding an invisible instrument—is quite an easy matter, requiring no power on the part of the teacher to command any "utterance of harmony" from it himself, nor any skill on his part! S'blood! are man's nerves and muscles easier to be played upon than tempered scales and ivory keys? It is not so, and only because custom sanctions the mode is the fallacy obscured, and the ignorance condoned—for Ignorance is the mother of stupidity, and Custom the father of fraud.

I cannot close these papers without publicly expressing

(a) Probably this physiologico-æsthetic fact, taken in connection with Dr. Wollaston's discovery of the *sursumus* of muscle, and the additions to this by Dr. Houghton, of Dublin, and Dr. Collingue, of Paris, may give the scientific basis for the solution of the much vexed question of "pitch." Hitherto the arguments of musicians have been confined to personal preference, bold assertions, and arbitrary coercion, and at such arguments scientific men can only smile.

my thanks to the Editor of the *MEDICAL PRESS AND CIRCULAR* for the kindness he has shown in allowing me, an outsider, the opportunity of expressing the results of my research in this much-neglected study of human voice; especially do I feel this kindness the more when I reflect that in consequence of my convictions I have been subjected both from the ignorant members of the musical profession and the Birmingham Press to a persecution which contrasts strangely with the generosity of a distant journalist: being so, it is natural that I should turn to a profession in which scientific research and self-abnegation have ever reigned supreme; and if by my writings I have added to the permanent store of human knowledge, I shall always feel deeply grateful to him who has permitted me herein to do so.

## Hospital Reports.

### CASHEL UNION HOSPITAL.

(Under the care of Dr. LAFFAN.)

OPHTHALMIC NOTES, BY MR. DWYER.

#### *Entropium.*

SEVERAL cases of entropium have been under treatment within a comparatively limited period. In some of these one lid only was affected; in others all four were involved. Some of the cases belonged to the acute, and others to the chronic form of the disease. The cornea were more or less injured in all. Dr. Laffan treated these cases by the removal of oval flaps of integument and muscle from the margins of the lids. Sutures were at the same time inserted into the sides of the incisions.

These, though they gave the patient additional pain, were found necessary. The results were in every case satisfactory. Dr. Laffan has had many of these cases under observation for a lengthened period, and the cures have continued perfect. The particular operation employed answered admirably in these cases; but a superiority over all others is not pretended for it in any case; while there are, of course, some to which it would be entirely inapplicable.

#### *Staphyloma.*

A GIRL, æt. 20, was admitted with complete and recent staphyloma, following extensive ulceration of the cornea. The mass projected a full inch behind the margins of the lids, was the cause of great deformity, and kept up a constant inflammatory condition of the conjunctiva. Although it seemed a case for the removal of the tumour, and the only question was the choice of operation, Dr. Laffan resolved to give a trial to a milder measure, and one which, if successful, would leave the minimum of deformity. He determined to subject the tumour to a combined process of pressure and paracentesis. A fine cataract-needle was accordingly inserted on each alternate day into the tumour, and the aqueous humour evacuated. Firm pressure was kept up in the intervals by means of pads. The result was entirely satisfactory. The cornea, or what remained of it, got time to consolidate, and all trace of the staphyloma disappeared. The minimum of deformity was realised, and even a certain amount of vision was obtained from a small bit of the cornea, which was unaffected by the inflammation.

#### *Cancer—Excision of Eyeball.*

J. W., a female, æt. 60, was admitted suffering from what appeared to be cancer of the eyeball. The local appearances corresponded to no described form of the disease. The organ was removed in the usual manner, and the parts soon healed. Secondary cancer, however, set in after a few weeks in the liver, and to this the patient succumbed.

A similar case, quoted from Laurence, is mentioned by McKenzie in his work on diseases of the eye.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 26, 1874.

### THE FINANCES OF THE MEDICAL COUNCIL.

AMONG the various questions suggested by the late proceedings of the General Medical Council recurs one that we have spoken of in other years—viz., is the Council worth its expense? It is to be remembered that the cost of this body is entirely defrayed by the profession. Its use is greater to the public than it is to us—in fact, it would be difficult to say what use it actually is to the profession. To revise the standard of education is to benefit the public. To keep a register of qualified men is for the public protection. The power of protecting us from quacks is so limited as to be practically useless. Still we have to pay all the expenses; we may well, therefore, keep an eye upon them: and to enable our readers to do this we propose to repeat here the facts recorded by the Finance Committee.

From their statement it seems that the income of the Council in 1873 was £768 16s. less than in the year 1872. This difference was, however, almost entirely due to the exceptionally large amount of fees received for registration by the several Branch Councils in 1872, and not to any special decrease in the income of the year 1873, which was not below the average. The balance in favour of income in 1872 was £2,260 3s. 7d., whilst in 1873 the balance amounted to only £212 17s. 6d. This difference is due to the fact of the Council having sat during only five days in 1872, whilst in 1873 the sittings of the Council extended to nine days. It may well be asked whether the work could not always be done in the shorter period. A sum of £598 10s. was expended in 1873 on account of the visitations of examinations. A further sum of £301 18s. has since been paid on account of these visitations, which will be included in next year's account, making the entire cost of the visitations £900 8s. With respect to estimate for the present year, the income will probably not be less than that of the preceding year, whilst the estimated expenditure has been necessarily increased to meet the charges which will accrue in connection with the occupation of the new premises. Doubtless other new expenses will crop up, and therefore care ought to be exercised. We cannot but think that this year the proceedings could have been got into a single week, which would have saved a respectable sum. The clerks to the Council will, in the

new building, have new work, and it is reasonable to afford them increased remuneration. Indeed, considering how much of the real work they do, and how well they do it, this must be anticipated. The Pharmacopoeia, too, will want more expense. The miserable addendum has cost a most unreasonable sum, and we sincerely hope that care will be taken not to waste money in such a way in the future. Anyone who looks into the expense of that little volume will be surprised. We should have thought that such a book could have been turned out for a trifle; but the amount spent on the chemistry of it alone is an example of extravagance that ought to be remembered.

Again, we say the finances of the Council should be looked after.

## Notes on Current Topics.

### An Ant-Cloud.

ON the 18th instant Cambridge was visited by an ant-cloud, the rare phenomenon occurring about six o'clock in the evening, and causing considerable annoyance to persons in the streets, the ants falling in countless millions about the pavements, and in the gardens and College courts. There were three kinds of ants, the great majority being the small winged male. Some of the larger ones were nearly half an inch long. Correspondents writing from Putney, Lewisham, Eltham, Southall Station, Ealing, Bexley Heath, &c., report that they observed in the roads and foot paths vast quantities of winged and wingless ants on the same evening.

### Dublin Main Drainage.

AT a special meeting of the Corporation, held last week, in reference to the above matter, it was resolved that the Council shall select three engineers to consider the subject, and report to a committee of the whole house, within two weeks from the date of their appointment; and as there are upwards of one hundred plans to be examined, these gentlemen will have an arduous duty to perform within a very limited period. We fear, therefore, that there is little chance of anything practical being done this year to remedy the present disgraceful condition of the drainage of Dublin; and we are afraid that in a few weeks the whole affair will be put aside until next summer again brings it into prominence.

### Hydrophobia.

A YOUNG man died at Brighton on August 14th from this cause. Early on the morning of the 13th, deceased felt unwell, and medical assistance was obtained, but it was found impossible to get him to swallow any medicine. Hearing that he had been bitten by a dog three weeks ago the suspicions of Dr. Rugg were aroused as to the nature of the case. He accordingly pressed him to drink a little brandy and water, but it was no sooner put to his mouth than he was seized with convulsions, and sprang up in his bed in a raving manner. He evidently wished to drink it, but was quite unable to do so. Seeing the danger of the case, Dr. Rugg called in Mr. Furber and Dr. Withers

Moore. They concurred in the opinion that it was a genuine case of hydrophobia. Chloroform was administered several times during the day, but it had no effect.

### The Professorship of Chemistry in Glasgow University.

THE Crown has appointed Mr. John Ferguson, M.A., to the Chair of Chemistry in Glasgow University, vacant by the retirement of Dr. Thomas Anderson. Mr. Ferguson has for some years been assistant to Dr. Anderson, and has of late performed the almost entire duties of the Chair, on account of the illness of Dr. Anderson.

### The Peculiar People.

THOS. HINE was tried on Wednesday last at the Central Criminal Court, before Mr. Baron Pigott. The charge of manslaughter of the child was not pressed, and at the close of the evidence his lordship expressed an opinion that no culpable negligence had been proved against the prisoner, and that the mere omission to call in a medical man in such a case did not amount to a criminal offence. The jury, therefore, returned a verdict of not guilty, and the prisoner was discharged.

### Absence of the Nose in a Child.

DR. ZOELLNER, of Schesslitz, communicates to the *Allgemeine Medizinische Central Zeitung* the following remarkable case of malformation:—

"On July 15th there was shown to me a child five days old, the subject of the following malformation. From the upper lip as far as the nasal bones, which project as in normally formed children, there is seen only a flat surface of skin, without furrow or opening. There is thus no trace of *alæ nasi*, nostrils, or nasal cartilage. The child is in general well developed. Nothing especial is to be observed in the mouth and fauces; but the *frænulum* of the upper lip is much developed. The principal point of interest is the mode of respiration. The child does not hold its mouth constantly open, as one would expect, but at short intervals separates the lips about a line from one another. The breathing is predominantly costal. If the lips be forcibly held apart for some time, in order, for instance, to examine the mouth and fauces, the child, after the removal of the finger, presses the lips firmly together for some seconds. The child is, of course, fed by hand, as sucking is impossible."

### French Association for the Advancement of Science.

THE annual meeting of this Association is being held in Lille, during the week from August 20th to 27th. Contributions have been promised by a large number of members of the medical profession, among whose names we notice those of MM. Bédard, Broca, Charcot, Chauveau, Lefort, Leudet, Marey, Ollier, Roger, Sée, Trélat, Verneuil, Wurtz, &c.

### Fees to Coroners.

A RETURN to the House of Lords, obtained by the Marquis of Salisbury, and recently issued, shows the payments made out of the county rates in respect of the disbursements of each of the coroners for the county of Middlesex during five years, from the first of July, 1869, to the 30th of June last. In the period Dr. Diplock re-

ceived respectively—£1,048 16s. 6d. in 1869-70, £1,118 18s. 8d., £1,278 5s. 6d., £1,424 9s., and £1,381 18s. 6d.; Dr. Lankester, £3,847 5s. 4d., £4,620 6s. 6d., £3,894 14s. 6d., £4,098 4s. 6d., and £4,144 8s.; Mr. Humphreys, £2,816 14s. 6d., £2,932, £2,929 5s., £2,985 9s. 4d., and £3,145 16s. 1d.; Mr. Bedford, £689 16s. 6d., £728 18s., £735 2s., £795 15s. 6d., and £705 1s.; and Mr. Payne received in the several years £64 14s. 10d., £97 9s. 8d., £62, £102 6s. 6d., and £93 9s. 6d.

### Questions at the Royal College of Surgeons.

THE following questions were given at the recent examination for the diploma of Member at the Royal College of Surgeons:—

#### Medicine.

1. You are summoned to an adult patient in a state of coma, and of whom you have no history. How would you proceed to examine the case so as to determine its nature? What are the chief causes of coma?

2. What are the diseases with which enteric fever (typhoid) is liable to be confounded in its earliest stages? By what symptoms would you be guided to a diagnosis in doubtful cases? What symptoms would make your diagnosis certain? What are the chief sources and indications of danger in this disease?

3. Give the medical properties of the following preparations, and the doses in which you would use them: Tr. digitalis, zinci sulphas, ext. belladonnæ, ext. ergotæ liquidum, ol. terobinthinæ, liq. arsenicalis, succus conii.

#### Surgery.

1. Describe the boundaries of Scarpa's triangle, and mention what tumours or swellings you may meet with in this region, and how you would distinguish them.

2. In what stages of their course may burns prove fatal? State what are the causes of death in each stage.

3. What are the causes and symptoms of perineal abscess? How would you treat such a case, and what consequences may result from its neglect.

4. What injuries are likely to result from a violent fall on the palm of the hand, with the arm raised and extended? Explain the mechanical mode in which such injuries are produced.

5. Describe the operation of placing a ligature on the brachial artery in the middle of the arm; and state by what vessels the circulation is re-established collaterally, and how the separation of the ligature is effected.

6. Describe, in their respective relations to each other, the various parts which must be divided in circular amputation of the leg, where the bones are sawn through immediately below the tubercle of the tibia.

### The Royal National Hospital for Consumption, Ventnor.

THE Earl of Strafford has just munificently contributed the amount necessary to become a donor of one of the sixteen hospitals or houses of which the institution is composed. This hospital is to be called "The Lady Agnes Byng's Hospital," in memory of the Earl of Strafford's first wife, Lady Agnes, fifth daughter of Henry, Marquis of Anglesey, K.G.

All the hospitals or houses are now either built or in

course of erection, excepting the two subsidiary hospitals. Funds, however, are still urgently required for many works still necessary, and for maintenance.

### Medical Microscopy.

AMONGST much other good matter in the last number of the *Quarterly Journal of Microscopical Science* are two useful papers (both read before the Medical Microscopical Society). The first, by Mr. Groves, of St. Bartholomew's Hospital, describes a new system of "Arranging and Cataloguing Microscopical Specimens." It is applicable to medium and large collections. Various systems have been proposed from time to time, but all have been deficient in one important quality possessed by that now under consideration—viz., facility of reference to any preparation or its component parts.

The principal features of this method are: 1st. A catalogue containing an alphabetical index to *everything* contained in *every* preparation, each reference being numbered according to the numbers on the slides. These are placed in the cabinet without any regard to arrangement, and simply numbered consecutively. This system can also be applied to collections arranged systematically, but in such there is generally loss of room, which is not possible in the original plan.

The second, by Dr. Baber, of St. Mary's Hospital, is on "Picrocarminate of Ammonia." It is entirely devoted to the most recent mode of preparation and employment of this staining fluid, invented by Ranvier, and largely used in the Parisian laboratories. The advantages claimed for it are, amongst others of minor importance, the property of staining tissues in a series of colours varying from red to yellow, of colouring rapidly and equally, and of being able to be kept in the dried form.

At a meeting of subscribers to the Livingstone Relief Fund, held at Glasgow on Thursday, a committee was appointed to collect money for the erection in that city of a statue to the late Dr. Livingstone.

MR. PETER MANNING was buried in the parish churchyard at Knighton, Leicestershire, last week, having attained the age of 101 years. He was a master framework knitter, and had been a Wesleyan local preacher for seventy years.

WITH regard to the report that there had been a fatal case of European cholera at Hanwell Asylum, a letter was read at the meeting of the Brentford Sanitary Board, on Wednesday last, showing that the death had arisen from other causes.

THE medical officers of the Islington Board of Guardians presented a memorial to the Board, asking a modification of the work, in consequence of parts of the district being very isolated, whilst in other portions the work of visiting was comparatively easy and quickly made. The Board declined to make any alteration in the rate of remuneration or the redistribution of duty.

NEARLY 2,000 calculi were exhibited at the Norwich

meeting, amongst which were—a stone weighing 15 ounces, successfully removed at the Norwich Hospital; a mulberry stone, weighing  $8\frac{1}{2}$  ounces, removed by Mr. Allen, of Norwich; a renal calculus from the right kidney, weighing  $36\frac{1}{2}$  ounces; and an enormous white oxalate of lime stone of undetermined weight, preserved in the kidney.

ONE of the guardians of the Spalding Workhouse recently performed in the character of a "sturdy rogue and valiant beggar," or, as we now say, a "casual." It had been objected by the Rev. Mr. Jones that the amount of work exacted from a casual in return for his food and lodging, viz., the breaking of two cwts. of granite in four hours, was too much, and, in fact, amounted to cruelty. Mr. Brett wasted no breath in words; he commenced his argument by taking off his coat, then proceeded to one of the tramps' cells, seized a hammer, and broke triumphantly two cwts. of granite in, not four hours, but one hour and forty-five minutes.

## THE BRITISH MEDICAL ASSOCIATION.

THURSDAY, AUGUST 13.

THE British Medical Association resumed its sittings, when an Address on Surgery was given by Mr. W. CADGE, F.R.C.S., Surgeon to the Norfolk and Norwich Hospital.

MR. CADGE observed that the novelties of surgical practice introduced during the last year or two were scarcely important enough to constitute a theme. They were chiefly comprised in Esmarch's bloodless system of operating, and Dittel's elastic ligature. Concerning these, he (Mr. Cadge) would only say that the first was not a novelty, having been practised by one of the members of the association many years since. The second was, in his (Mr. Cadge's) opinion, more curious than useful, and not worthy of a place either in the records or in the practice of surgery. There was one great subject which, if not exactly a novelty was of recent time, and was still waiting for a solution, both as to its facts and as to the theories held to account for its facts—he meant the germ theory of putrefaction and antiseptic surgery. This subject he considered of surpassing importance and interest. Underlying, if not undermining much of the existing fabric of surgical pathology and practice, it could not be too often brought to the bar of professional criticism; for on its right solution, whether it was true or not, depended a multitude of points in daily practice, and even probably the lives of many of our fellow-creatures. The remainder of Mr. Cadge's paper was devoted to an elaborate examination of stone disease. Incidentally alluding to the importance of milk for the support of young children, Mr. Cadge observed that it would be a glorious result of statecraft if, instead of the futile wrangling over the sale of fermented liquors, which had wrecked one powerful government, and by the disappointment of greedy expectants had gone far to sap the popularity of its successor, by some equitable enactment those who possessed and occupied the land should be held responsible for the production in sufficient abundance for the wants of the poor of that which was now a costly luxury, but which nature pointed out to be the chief—he might say the only need of early childhood.

A cordial vote of thanks was accorded to Mr. Cadge for his address.

A report was presented by the Parliamentary Bills Committee. The report stated that the committee had been further engaged in pressing upon the attention of the Government the claims of the medical officers of the army and navy to improved relative rank, pay, promotion, and retirement,

very full and complete information having been laid before the committee, derived from communications from officers of all ranks.

Professor HUGHES BENNETT made a statement as to the antagonism of medicines—hydrate of chloral and strychnia, sulphate of atropia and Calabar bean, hydrate of chloral and Calabar bean, sulphate of atropia and meconate of morphia, meconate of morphia and infusion of tea, meconate of morphia and theine, meconate of morphia and caffeine, meconate of morphia and quinine, meconate of morphia and infusion of coffee, extract of Calabar bean and strychnia, hydrate of bromal and atropia, &c. The statement was received with much attention, and elicited a hearty vote of thanks.

In the Public Medicine Section Mr. W. H. MICHAEL again presided. A discussion took place on a paper read by Dr. Beverley on the preceding day on hospital hygiene, with especial reference to the Norfolk and Norwich Hospital, in which a large amount of pyæmia has prevailed lately.

Dr. BEVERLEY replied. He stated that measures were being adopted to cleanse one of the walls of the Norfolk and Norwich Hospital. The question of economy must, of course, be considered; but still human life must not be sacrificed, and it would be better to have a small and thoroughly efficient hospital rather than a large and inefficient one. Some other points having been noticed by Dr. Beverley, the discussion closed.

Dr. C. J. FOX read a paper on water analysis as it should and should not be performed by the medical officer of health. Dr. Fox observed that the elementary principles upon which the greater part of the work of the medical officer of health was based might be said to be the prevention of water pollution and of air pollution with the products of decomposing filth. The examination of drinking water formed a very important portion of his duty in his crusade against preventible disease. The most rough and ready way which has been employed for ascertaining whether or not a water was polluted with organic matter was to partly fill a clear bottle with a sample of it, and having violently shaken the same, to take a hearty sniff at the air of the bottle which had been agitated with the water. If the air smelt sweet and fresh the absence of an injurious amount of organic matter was inferred, and *vice versa*. It should be borne in mind that the existence of an unpleasant odour or taste about the water from a well sunk through certain kinds of clay was no proof of the pollution of water with organic matter. Water, if allowed to remain long in contact with certain kinds of clay, acquired such an objectionable smell as to be sometimes quite undrinkable, and yet might not at the same time contain an amount of organic matter which would warrant its condemnation. A well of this kind could be made to furnish excellent water by the frequent withdrawal of its contents, or if that was not practicable, by filling up the dry portion of the well and by drawing the supply solely from the bore-pipe. Dr. Fox, in closing a paper of considerable length, said his great object in bringing the subject of water analysis before the association, which numbered among its members so many medical officers of health, was the hope that some uniform plan of examination might be adopted by all.

FRIDAY, AUGUST 14.

The Address in Obstetric Medicine was delivered by J. MATTHEWS DUNCAN, M.D., which will be found at page 174.

Dr. J. MARION SIMS (America) moved:

"That the best thanks of the Association be given to Dr. Matthews Duncan for his able and interesting address in obstetric medicine."

After a reference to Dr. Barker of America, whom he named as the Duncan of the States, the speaker made allusion to the complete system of registration of the cause of death in New York. He then asked leave to speak of the American Medical Association, and said that as Americans imitated England in everything, they twenty-

five years ago founded an Association. This had gone on and had published volumes of "Transactions." Two years ago, after the Association had been going on as well as could be expected, at the annual meeting at Philadelphia, he was ashamed to say, five hundred grave and learned men for twenty-four hours discussed everything but science—the woman's question, the question of negro doctors, and such like; and the Association nearly split upon these rocks. A few wise heads, however, advised that these questions should be relegated to a judicial committee, and at the last meeting the whole proceedings were most harmonious, there being present men from all parts, and representatives from Canada, and nothing but science was talked. He was glad to state this, showing that the American institution was forming itself on the basis of the British, and, in his opinion, the nearer the American came to its British model, the nearer it would be to perfection. (Cheers.) He then moved the resolution of thanks.

Mr. MASTER seconded the resolution, which was carried unanimously.

Dr. DUNCAN, in acknowledging the vote, said that he had shown that women, when they married and had children, underwent great perils; but, if he had gone to the other picture, of the women who married and had no children, it would be seen that they were in danger of more fearful perils still.

Sectional meetings were then held.

The concluding general meeting was held in Noverre's Rooms, at 1.30 p.m.

*The State Medicine Qualification Committee.*—Dr. RUMSEY, in resuming this subject, submitted that it would be advisable to make some provision for the adjournment of this question either to a general meeting or to the next year. He thought that some opinion should be expressed before the next session of Parliament; but, as he could not see his way to ask the meeting to adopt the draft report, there being differences of opinion on the committee, he thought the difficulties would be overcome if the report could be referred to three men to act as arbitrators, as Dr. Lyon Playfair, as representing Parliament, Mr. George Hastings, as representing law, and the Rev. Dr. Haughton, as representing Ireland.

Dr. FALCONER moved that the report be referred to the Committee of Council, saying that he had no doubt, if that course were adopted, the suggestion of Dr. Rumsey would be taken into consideration.

Dr. RUMSEY said he was quite agreed to take that course.

Dr. ARMISTEAD seconded Dr. Falconer's proposition, and this was agreed to unanimously.

Dr. BATEMAN (Norwich) proposed, and Mr. SOUTHAM (Manchester) seconded:

"That the cordial thanks of the British Medical Association be given to J. J. Colman, Esq., M.P., for his great hospitality in giving a *déjeuner* in the grounds of Carrow House."

Dr. FALCONER proposed, and Dr. RUMSEY seconded:

"That the warmest thanks of the Association are due, and are hereby given, to Dr. Copeman for his services in presiding over this the forty-second annual meeting of the British Medical Association."

He congratulated the President upon the success of the meeting under his auspices. There was not one member of the Association at Norwich to whom Dr. Copeman had not been desirous of showing some personal courtesy, and, if any had been overlooked, it was by accident, and not by intention. (Cheers.)

Dr. RUMSEY seconded the resolution, and said that though it did not need any recommendation, yet he could not help saying that the fortunate election of Dr. Copeman showed the advantage of taking as President the chief man of a locality, and was a proof in favour of the Association's present mode of selecting its Presidents.

Mr. SOUTHAM put the resolution, which was carried amid general cheers.

The PRESIDENT acknowledged the vote, and said it had

been a week of work to him, but it had been one in which he had received more information and matter for reflection than he could have received in years of study. He thanked on his part all who had endeavoured to increase the scientific knowledge of their brethren, and improve the science of medicine generally. He was sure that no medical man could have come to the meeting without learning something, or taking back with him some thoughts for future study, and thus the meeting would happily advance the medical art. (Cheers.)

## THE AMERICAN MEDICAL ASSOCIATION.

THIS great organisation has held its annual congress this year at Detroit, and it may be worth while to take some notice of its proceedings at a time when its British sister is furnishing a similar holiday in this country. We do not propose to contrast the two associations, as we should find our own to be rather inferior in many respects.

After the Presidential Address, in which there was a sketch of the history of the association, routine business was transacted.

The next most interesting event was the Report of the Judicial Committee on the question of a general revision of the Code of Ethics, which is supported by all the influence and power of the association.

The committee considered that the objectors to the present code could be divided into two classes: firstly, those who looked upon the code in the light of ordinary by-laws, and who regarded all in the present code relating to the duties of patients to physicians, of the public to the profession, and of the profession to the public, as superfluous, who would retain only so much as related to the intercourse of physicians with each other. To these the committee would reply that the Code of Ethics is more than a series of by-laws, that it does not attempt to give rules applicable to every case, but does attempt, and is well adapted as it now stands, to give the principles by which the duties of both physicians and the public should be regulated.

The second class of objectors to the present code do not object to it as a whole, but wish certain alterations, principally in those parts relating to two subjects—viz., specialities and bestowing professional services by contract. In regard to specialities, the committee considered that if specialists are members of the profession they must be governed by the same principles of action as the whole profession. Special practice is simply a self-imposed limitation of duties, and should be indicated not by special titles, as "oculist," "gynaecologist," &c., but by a simple notice appended to the ordinary card of the physician, saying "practice limited to diseases of the eye," &c. In regard to the bestowal of services by contract, the present code sanctions gratuitous service to the poor, whether singly or in charitable institutions, but forbids such service to other institutions which are able to pay. Although such institutions may pay the physician a certain sum per annum, yet such a method of payment violates the principle that the physician should be paid for services rendered.

Charitable institutions should not bid for the lowest bidder, but fix a salary and get the best man who is willing to take it at the price offered. The committee therefore recommended that the present code remain unaltered.

A resolution was passed unanimously adopting the report.

A committee on the rank of the medical staff of the army reported that they had memorialised congress; the memorial had been twice read and referred to the military committee, who have as yet taken no action upon it.

The annual address on practical medicine was delivered by Dr. N. S. Davis, chairman of the section on practical medicine, materia medica, and physiology.

In a future number we propose to publish a portion of this address.

Dr. S. D. Gross, of Philadelphia, chairman of the section on surgery, read an interesting report upon the subject of syphilis.

The principal points in his address were that there is no

duality of poison in this disease; that the virus of hard and soft chancre is identical. A long and elaborate historical argument was presented to sustain this view. Then, the vast number of persons directly or indirectly affected by syphilitic taint was graphically depicted. To rescue the race from the effects of promiscuous sexual intercourse he advocated a compulsory medical examination of prostitutes.

Dr. A. N. Bell, of Brooklyn, read an address on "The Waste of Life," taking for his text the sentence from Taylor's Medical Jurisprudence—"It is held in law that whoever accelerates death causes it."

The speaker mentioned the wide-spread and well-known existence of preventable causes of death. Notwithstanding the knowledge of the existence of these causes, and the knowledge of their preventability, the community quietly suffers their continuance, except when temporarily aroused by some shocking disaster. Much is then said, but little done. But, even worse than the causes of sudden death are those of slower action. Houses are built over old cesspools; halls of assembly are built with imperfect ventilation; country dwelling-houses are often surrounded by stables, cesspools, and wells, in close proximity to each other.

Tenement houses are built in which whole village populations live, where cleanliness is next to impossible, and the natural consequence of dirt is loss of health, loss of self-respect, then degradation and crime. One-half of the children born in New York are born in tenement houses, and New York is a Christian city! The argument that these causes of death only serve to remove a superfluous population, and so leaves more of the common stock of the materials of life for those who are left, is erroneous. For a great portion of these deaths are among the young, and, up to fifteen years, children are consumers and not producers, hence, all who die before that age, fail to produce any part of the common stock. Again, when adult men die, they leave usually widows and orphans, who, being for the most part simply consumers, fall back upon the State.

Dr. E. Seguin, of New York, as delegate to foreign medical societies, reported that he had attended meetings of certain English and French societies, where he had advocated the establishment of a harmonious method of clinical observation.

In the section on practical medicine, materia medica, and physiology, Dr. Bulkley, of New York, presented a paper on "The Management of Eczema," the principal points of which were that eczema differs from an ordinary dermatitis in being a true catarrhal dermatitis, and in depending not merely upon local, but upon constitutional causes. In a simple dermatitis, the removal of the cause and prevention of further irritation suffice to a cure, but in eczema the dermatitis runs a definite course. Debility alone does not cause the tendency to eczema, but some blood change, represented in the main by a state of sub-oxidation, or hyper-acidity, a condition allied to that of gout, rheumatism, scrofula. Acute eczema is self-limited. In the chronic stage we have to do with the products of inflammation. Treatment varies accordingly.

Although a constitutional disease, local treatment is important. In the acute stage indications are, removal of local causes, prevention of irritation. In the chronic stage, Dr. Bulkley warmly recommended his "liquor picis alkalinus," which has the following composition:—

R. Caustic potassa, 3j.;  
Tar, 3j.;  
Water, 3v.

In preparing this the potassa is dissolved in the water, and this solution poured upon the tar in a mortar, and mixed. This remedy should always be used diluted, except where a strong application in very chronic cases is desirable.

Constitutional treatment is of prime importance. Arsenic is a valuable remedy, but by no means a specific one. The treatment should be dietetic, hygienic, and medicinal. Diet should be simple; fresh air, cleanliness and rest should be secured. Medicinal treatment embraces diuretics, to relieve the skin; alkalies are rationally indicated, to counteract the hyper-acidity of the blood; quinine, strychnine, iron, acids and arsenic should be given as tonics. Cod-liver oil is more nearly a specific than anything.

This paper was very thoroughly discussed by the section, and recommended for publication.

Dr. D. J. Farnsworth, of Iowa, then read a paper upon "The Therapeutics of Ammonia," which we intend to publish, at least, in abstract.

Dr. Reuben A. Vance, of New York, read a paper on "The Mechanism of the Encephalic Circulation."

His conclusions as to the peculiarities of cerebral circulation are condensed as follows:

1. Atmospheric pressure operates in such manner as to keep the fluid contents of the skull at all times the same.

2. The heart can, under certain circumstances, exert a compressing influence upon the encephalic structure; and,

3. The relative quantities of arterial and venous blood and extra-vascular serum vary with cardiac contractions, respiratory movements, sleep and wakefulness, and mental excitement and repose.

Dr. F. R. Buckram read a paper on "Uræmia," in which, from an extended series of experiments, he concluded that uræmia existed in very many cases where no albuminuria could be found; that this condition exists much more frequently than is usually supposed, and is the cause of many of those phenomena of disease which are as yet ill understood, and often of an undefined nature. Such he considered to be the probable cause of muscular rheumatism, neuralgia, the muttering delirium of low fevers, &c.

In the section of obstetrics and gynecology several discussions took place, one of them, on "Transfusion," Dr. Parvin exhibiting some instruments for this operation, and another on ovariectomy.

In the section on surgery and anatomy, Dr. A. Dunlap, of Springfield, Ohio, read a paper detailing the history of a case of "Enchondroma over the Sternum," and Dr. E. M. Moore, of Rochester, one on "Epiphyseal Fracture of the Superior Extremity of the Humerus."

Prof. Sayre, of New York, reported on the subject of "Fractures." His principal points were—(1st.) That surgeons should never, as was the old custom, wait nine days for the swelling to subside before setting a fracture. (2nd.) That the generally accepted idea that in oblique fractures of the long bones we were to expect deformity, is erroneous, and the sooner corrected the better. (3rd.) All that is necessary in any fracture is extension and counter-extension in the right direction, so as to have accurate adjustment. (4.) If extension greater than normal is made, it would cause reflex contraction and irritation, but if we only use extension until the normal length is reached, and then retention, all will be quiescent.

He said it made little difference how this extension and how this retention are made, provided that they are made—plaster of Paris, starch, soluble glass, splints—the methods may vary, the principle is the same.

In support of his statements the speaker adduced the measurements in 115 cases treated in Bellevue Hospital. Some of these were lengthened, some without shortening, some with a shortening of one-sixteenth to one-eighth of an inch. Excluding three cases, which had, one two inches, a second one and three quarters, the third one and a half, these cases suffering respectively from abscess, delirium tremens, and pneumonia (which being kept horizontal had permitted shrinkage, and hence shortening)—excluding these, a very highly favourable average had been obtained.

A long discussion then took place, in which Dr. Hodgen, of Missouri, objected that if a thigh be extended in a plaster of Paris splint, the muscles on the back would be tense, while those on the front would be relaxed; that it is impossible to secure the same degree of tension in all the muscles, hence there must always be irritation of the soft parts. Dr. Sayre replied that it was possible; in fracture of the femur treated upon the inclined plane, we must have a thigh-piece capable of being shortened or lengthened. Dr. Gregory, of St. Louis, was astonished; he thought Prof. Sayre's results barely possible, and wanted further evidence. He maintained that there can be no union of either soft or hard parts without shortening, owing to the resorption of the parts next to the lesion, which constitutes a part of the reparative process. There is no scar without contraction. Dr. A. Garcelon spoke of the great practical importance to the entire profession of the statements of Prof. Sayre. He agreed with Prof. Sayre in aiming at exact apposition, but doubted the possibility of its attainment in the degree mentioned by Prof. Sayre. He further alluded to the difficulties of accurate measurements. If the position taken by Dr. Sayre is accurate, the profession has much to learn, and the public much to complain of. Dr. Gross said he preferred the solution of silicate of potassa or of soda to plaster of Paris in making his bandages. He believed that a certain amount of shortening was necessary in oblique fractures of the femur. Dr. Reed, of Ohio, believed there is always shortening; alluded to the fact that he had never seen a skeleton in which the corresponding bones (though never

broken), were perfectly equal in length. Dr. Whiting, of Wisconsin, was alarmed at Prof. Sayre's statements. The records of the profession for the past fifty years do not lead us to expect such results as those reported from Bellevue Hospital. If Prof. Sayer was right, he would, in self-defence, be compelled to retire from the profession, as would many others. Dr. Waterhouse, of Wisconsin, said if these statements are true and these figures accurate, then let us face the situation, and let the danger of suits come. There is a reason for this unheard of success at Bellevue in the appliances at hand, and the constant attendance and care available, which country practitioners can never enjoy, and suits for malpractice are generally brought in the country. Back-woods doctors scarcely ever have proper appliances, and cannot possibly give cases constant personal care. Dr. Pierce, of Illinois, thought that the facts should be made known, and if surgery has made such advances, it should be declared. He believed that Prof. Sayre's measurements had been made too soon. Shortening goes on after discharge, and when the limb has been brought into use. He advocated the Bavarian splint. Dr. Sayre said that he *knew* his measurements were correct; that Dr. Frank Hamilton had made the measurements, and that he was a man who was so violently opposed to the theory that, in his published writings, he had denied the possibility of any oblique fracture being cured without shortening. For this reason he (Dr. Sayre) had asked him to measure the patients. He said if seven successive cases would be presented, he would agree to give up his opposition to the theory. He found the cases, and surrendered.

A resolution was passed to the effect, that the results of the treatment of fractures as made public in Professor Sayre's paper, are better than can be looked for in general practice.

Dr. George M. Beard, of New York, read a paper upon the uses of electricity in surgery, advocating its use in goitre, in benignant tumours, mentioning its favourable effects in certain cases of epithelioma and scirrhous. He also advocated its use in certain diseases of the skin.

## Correspondence.

### ON THE THEORY OF COUNTER-IRRITATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have only just seen Dr. Drysdale's letter which appeared in your issue of August 5, otherwise I would have replied to it sooner. Dr. Drysdale is mistaken in thinking that I was "unaware of having been preceded by Fletcher" in the belief that counter-irritants act by stimulating the diseased part. I adopted this view myself when a student, and very naturally thought that it was entirely original, and a letter from me, in which the stimulant action of counter-irritants was distinctly enunciated, appeared in the *British Medical Journal* for 1863. Several years subsequently Dr. Dickenson opened a controversy on counter-irritation, and when Dr. Anstie, who took part in it, spoke of the stimulant action of blisters, I put in a claim of priority. Dr. Anstie, in reply, said that he did not think the point of much consequence, but that he had given expression to the same opinion several years before I did. It is, therefore, true, as Dr. Drysdale says, that Dr. Anstie claimed priority of me, but nowhere that I know of did he claim priority of every other one, and pretend that the idea was exclusively his own. In a subsequent communication to the *Practitioner* I renounced all claim of priority to the idea; but as I am not at home at present I cannot give Dr. Drysdale the exact reference. About this time I found that Dr. Graves held the same opinion, and my friend, Mr. Pope, called my attention to Fletcher's view.

On finding that the belief in the stimulant action of counter-irritants was more widely diffused than I had previously any idea of, I have since continued to use the conception as the common property of the profession, and I have not associated it with the name of Fletcher or with any other name, because I do not even now know whether or not the view was original on the part of Fletcher. But if Dr. Drysdale will prove, not merely that the conception is to be found in the writings of Fletcher, but that it is not to be found in any anterior writings, then I will in future associate his name more closely with the idea than I have hitherto done. Had I been giving an historical account of the genesis of the conception I should have been culpable had I failed to mention the name of Fletcher;

but as my object was to utilise the idea for a specific purpose, and as I had previously made a formal and public renunciation to all claims of priority, I did not deem it necessary to mention any name in connection with it. No one, of course, can blame Dr. Drysdale for endeavouring to obtain justice for the memory of a late friend and teacher, and I am not at all surprised that he has made my article the occasion for bringing Fletcher's views before the profession, and I hope that he will fully understand that I have not now and never had the slightest wish to detract from any merit due to Fletcher with regard to the subject. My own claim to originality respecting the theory of counter-irritation rests upon a different basis. I have, so far as I know (but even upon this point I would like to speak with some diffidence), supplied a new machinery by which the stimulant action may be supposed to travel from the source of irritation to the diseased part. Fletcher believes that it is mainly owing to an action of the vessels, while I believe, on the contrary, that it is chiefly due to the proper parenchyma of the part. Fletcher may be right, and I may be wrong; but our ideas respecting this part of the subject most assuredly differ very considerably.

I am, Sir, yours very sincerely,

Ashby Folville, Aug. 20, 1874.

JAMES ROSS, M.D.

### RAILWAY CASES—A SUGGESTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The conflicting medical evidence in railway cases has been sufficient of late to throw grave doubts upon its value. How a jury of even intelligent men can form an opinion or assess damages when the evidence of equally eminent members of the profession is so diametrically opposite I am at a loss to conceive, for a jury composed of medical men would have the greatest difficulty.

There are cases of this kind at almost every court of assize in the country, and the medical evidence is nearly always conflicting, and must be very perplexing to both judge and jury. We are aware that these cases present unusual difficulties; hence the varied but no doubt honest opinions expressed in our courts of law.

I read with surprise and regret the difference of opinion expressed in the last two cases, and fully agree with the remarks in your last issue; like you, "I do not see why, if a committee of competent physicians had adjudged upon the matter after careful investigation, they need have experienced any difficulty in arriving at the truth."

I would suggest in these cases that the jury, through the judge, should appoint a jury of medical men, consisting, say, of 5 in number, who had not previously seen the patient, that these should examine and report on the case for the benefit of the common jury. (Three of the members of the medical jury agreeing should be deemed sufficient, and their report accepted.) This report would be of the greatest value, and would assist the jury to form an opinion of the case and to assess damages.

The fee for such examination and report to be fixed on at the time, and in proportion to the amount claimed by the plaintiff, and paid with the other costs in the case.

If this plan were adopted we should have legitimate damages awarded, and should be saved the disgrace of seeing the conflicting evidence we have at present.

Every assize town would be able to produce a sufficient number of eminent men for the purpose, who would do justice to the parties concerned, and be appreciated by the general public.

I am, Sir, yours, &c.,

WM. BERRY, M.R.C.S. Eng., &c.

Wigan, Aug. 20, 1874.

## Medical News.

Royal College of Surgeons of England.—The following gentlemen having passed the required examinations for the diploma, were duly admitted members of the College at a meeting of the Court of Examiners on July 30th.

Frederick S. Alfred, Hampstead; Charles W. Belfield,

Bristol; George W. Bell, Hatfield; George H. Bishop, Harrow Road; John J. Byrne, Manchester; Bolton G. Corney, Kensington Road; Thomas H. Haslam, L.S.A., Finboro' Road; Lewis Jones, M.B. Dub., Aberystwith; Wm. A. Kennedy, Newcastle-on-Tyne; John J. Newman, Barnsley; Edward Noott, L.R.C.P.Ed., Dudley; Arthur Norton-Taylor, Maida Hill; John B. Sincock, L.S.A., Scorrier, Cornwall; Wm. Speirs, L.R.C.P.Ed., Glasgow; Samuel J. Thomson, L.S.A., Ramsgate; James H. Turtle, L.S.A., Chatham; Herbert E. Williams, Tavistock.

Of the 190 candidates examined during the fortnight, 44 failed to satisfy the Court of Examiners, and were referred to their professional studies for six months. This is the last examination for the Membership of the College until November.

**Apothecaries' Hall.**—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, August 6th, 1874: Brady, Owen Cornelius, Vernon Road, Birmingham; Mitchell, Charles Joseph Carter, Kempton, Bedford.

The following gentlemen also on the same day passed the primary professional examination:—

Calcott, Lewis Berkley, St. Bartholomew's Hospital; Haselden, Robert, St. Bartholomew's Hospital; Parkinson, Sidney George, St. Mary's Hospital; Pearless, Walter Relf, St. Bartholomew's Hospital; Upton, Alfred, St. Bartholomew's Hospital.

The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, August 13th, 1874:—

Harle, William John Vincent, Eagle Villa, Hackney; Horne, John Fletcher, Clarendon Road, Leeds; Snook, William Ernest, Colyton, Devon.

The following gentleman also on the same day passed his primary professional examination:—

Lucas, Arthur, Middlesex Hospital

**University of London—First M.B. Examination—Examination for Honours.**—**ANATOMY—First Class:** Kectley Charles Robert Bell (Gold Medal), St. Bartholomew's Hospital. **PHYSIOLOGY, HISTOLOGY, AND COMPARATIVE ANATOMY—First Class:** Tirard Nestor Isidore Charles (Exhibition and Gold Medal), King's College; Carrington, Robert Edmund, Guy's Hospital. **Second Class:** Kectley Charles Robert Bell, St. Bartholomew's Hospital. **ORGANIC CHEMISTRY, AND MATERIA MEDICA AND PHARMACEUTICAL CHEMISTRY—First Class:** Carrington Robert Edmund (Exhibition and Gold Medal), Guy's Hospital; Kectley Charles Robert Bell (Gold Medal), St. Bartholomew's Hospital (obtained the number of marks qualifying for the Exhibition); Burton, Samuel Herbert, University College.

**King and Queen's College of Physicians in Ireland.**—At examination meetings of the College held on Tuesday, Wednesday, and Thursday, August 4th, 5th, and 6th, 1874, the Licence to Practise Medicine was granted to—

Dane, Arthur Henry Cole Vesey Agmon Blathwayt; Hogau, Edward Michael Angelo.

The Licence in Midwifery was obtained by—

Gordon, Samuel Thomas Vesey, Agmon Blathwayt

The Licence to Practise as a Midwife and Nursotender was granted to—

Greenstreet, Miss Ellen M.

Miss Greenstreet is the first candidate who has presented herself for examination under the new bye-law of the College.

**Royal College of Physicians and Surgeons, Edinburgh—DOUBLE QUALIFICATION.**—The following gentlemen passed their first professional examination during the recent sittings of the examiners:—

William Deane Penier, Cork; Cecil Osburne, Cork; George H. Bentley, Bombay; John Hugh Maclean, Edinburgh; George Taylor Schofield, Yorkshire; William Perrin Brown, Warrington; Mackintosh A. J. Collie, Morayshire; Thomas Gallimore, Ashwood, Longton; Archibald Alexander Hamilton, India; James W. McGlade, Edinburgh; Hargreaves H. H. Hanson, Leicester; Walter T. Ramsden, Batley; William Henry Vickerstaff, Macclesfield; and John Mitchell Carr, County Armagh.

The following gentlemen passed their final examination, and were admitted L.R.C.P.E. and L.R.C.S.E.

Richard Wilkins, Madras; Wm. O'Hara, India; Richard Stratheden Dawson, India; George Benjamin Powell, Dublin; John Francis Herring, South Wales; Reginald

Hartley, Yorkshire; Hugh Alexander Auchinleck, Strabane; William M'Iver, County Tyrone; Marc d'Espaignet, Mauritius; Thomas Douglas, Northumberland; Fray Ormrod, Lancashire; John Edward Allen, Cheshire; James Bruce Ronaldson, County Cork; Rowland Cooke O'Meara, Dublin; Edward William Thomson, East Indies; John Walker Smyth, County Antrim; John Frederick Johnson, Monaghan; Nicholas Leader, County Cork; Walter Kavanagh Verling, County Cork; David John Ross, Galway; Thomas Horne, Whitby; Thomas William Myles, Limerick; Henry George Horace Naylor, Calcutta; James William Whiteford, Canada; Patrick Joseph Hayes, Cork; James Rutherford Morison, County Durham; and William John Vereker Bindon, Cape of Good Hope.

**Drogheda Medical Society.**—The anniversary meeting of the formation of this Society was held at Navan on Monday the 3rd inst. Dr. Hamerton was made President for the ensuing year, Dr. Delahoyde Vice-President, and Dr. Clarke re-appointed Secretary for another year. Addresses were delivered by the President and the Secretary. It was arranged that the area of the Society should be extended so as to include the whole counties of Meath and Louth, as several gentlemen wished to join who were outside the previously existing boundary.

**Army Medical Service.**—List of gentlemen who competed successfully for appointments as surgeons in H.M.'s Army Medical Service at the competitive examination held at the London University on the 10th August, 1874.

Dr. C. J. B. Williams has been appointed Physician-Extraordinary to the Queen.

Small-pox is said to exist in the Forest of Dean, and appears to be spreading.

## NOTICES TO CORRESPONDENTS.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

## VACANCIES.

Accrington and District Dispensary. Medical Officer. Amersham Union. Medical Officer for the Mismenden District. Salary, £34 per annum.  
Anderson's University, Glasgow. Professor of Chemistry. Applications, 1st September, to J. B. Kildston, Secretary.  
Birmingham General Dispensary. Additional Resident Surgeon. Salary, £130 per annum, rising to £150, £30 per annum for cab-hire, furnished rooms, &c. Applications, 29th inst., to A. Forrest, Secretary.  
Borough of Stockport. Medical Officer of Health and Borough Analyst. Salary, £150 per annum for one year.  
Bradford (Yorkshire) Eye and Ear Hospital. Assistant Surgeon. Salary, £52 10s. per annum. Application, 8th September, to William Maw, Secretary.  
Cancer Hospital. Resident House Surgeon and Registrar. Salary, £103 per annum, with board and residence. Applications, 27th inst., to the Chairman of the Weekly Board, 187 Piccadilly.  
Carlisle Dispensary. Assistant House Surgeon. Salary, £90 per annum, with apartments, coal, gas, and attendance. Applications to Mr. Davidson, Hon. Sec., 8 Devonshire Street, Carlisle.  
Garstang Rural Sanitary District. Medical Officer of Health. Salary, 21s. per case, and 61. per mile each way. Applications, 27th inst., to Thomas Noble, Clerk.  
Great Northern Hospital. House Surgeon. Salary, £63 per annum, with board and lodging. Applications, 28th inst. Also Physician-Surgeon. Applications, 15th September, to A. Phillips, Secretary.  
Hoxne Union, Suffolk. Medical Officer for the Hoxne District. Salary, £12 12s. 6d. per annum.  
Hull and Sculcoats Dispensary. House Surgeon.  
Hull General Infirmary. Resident Assistant Surgeon. Vacancy 1st September. Applications to W. Shepherdson, Secretary.  
King's College Hospital. Physician to Out-patients.  
Newcastle-on-Tyne Infirmary. Physician. Applications, 3rd September, to R. Y. Green, Secretary. Also Senior House Surgeon.

Queen Charlotte's Lying-in Hospital. Resident Medical Officer. Applications, 7th September, to A. Boodle, Secretary.  
 Bedford Urban Sanitary District. Medical Officer of Health. Salary, £50 per annum for three years. Applications, 27th inst., to R. Harwood, Clerk to the Authority.  
 Royal Cornwall Infirmary, Truro. Physician.  
 South Shields Urban Sanitary District. Medical Officer of Health. Salary, £300 per annum for three years. Applications, 27th inst., to J. M. Moore, Clerk to the Authority.  
 Western Ophthalmic Hospital, Marylebone Road. Two Surgeons. Applications to R. C. Wilson, Hon. Sec.  
 York Dispensary. Resident Medical Officer. Salary, £130 per annum, with apartments, coals, and gas.  
 Yorkshire Lunatic Asylum. Resident Medical Superintendent. Salary, £300 per annum, with house-rent and taxes free; coals, gas, vegetables, milk, and washing provided; £150 will be expended on substantial furniture.

#### APPOINTMENTS.

BRAILEY, W. A., M.A., M.D. Cantab., Curator of the Museum of the Royal London Ophthalmic Hospital, Moorfields.  
 CORNACK, J. C., L.R.C.P., House Surgeon to the North Dispensary, Liverpool.  
 CROWFOOT, E. B., M.B., Medical Officer to the Beccles Hospital.  
 CROWFOOT, W. M., M.B., Medical Officer to the Beccles Hospital.  
 HORNER, A. C., M.R.C.S., House Surgeon to the Kidderminster Infirmary.  
 JENKINSON, H., Esq., Senior Resident Medical Officer to the Leeds Public Dispensary.  
 JULIE, H. E., M.R.C.S., L.S.A., House Surgeon to the Female Lock Hospital and Asylum, Westbourne Green.  
 KEELING, J. H., M.D., re-appointed Surgeon to the Sheffield Public Hospital and Dispensary.  
 KEYWORTH, G. H., M.R.C.S., L.S.A., House Surgeon to the Buckinghamshire General Infirmary, Aylesbury.  
 M'GILL, A. F., Esq., elected Honorary Surgeon to the Leeds Public Dispensary.  
 MAGRATH, J., M.D., Assistant Physician to the Metropolitan Free Hospital.  
 MEDCALF, E. S., M.R.C.S.E., L.R.C.P. Ed., L.S.A. Lond., Resident Medical Officer to the Western Branch of the Brighton and Hove Dispensary.  
 METCALFE, R. L., M.D., Medical Officer to the Beccles Hospital.  
 NEEDHAM, F., M.D., Medical Superintendent of the Barnwood House Lunatic Asylum, Gloucester.  
 PRICHARD, A. W., M.R.C.S., House Surgeon to the Royal Westminster Ophthalmic Hospital.  
 ROGERS, M. C., M.R.C.S., Honorary Surgeon Dentist to the Western General Dispensary.  
 SMITH, J., M.D., Physician to the Dumfries and Galloway Royal Infirmary.  
 SPRATLY, S., M.D., Medical Officer to the Birkenhead Borough Hospital.  
 VERNON, W., M.R.C.S.E. (Demonstrator of Anatomy at the Westminster Hospital Medical School), Honorary Surgeon to the Farringdon Dispensary.  
 WATSON, M., M.D., Professor of Anatomy in Owen's College, Manchester.  
 WHITTLE, E. G., L.R.C.P. Lond., House Surgeon to the Hove Lying-in Institution, Hospital, and Dispensary for Women and Children.

#### Marriages.

BYERS-BOWMAN.—On the 20th inst., at the parish church, Bishopwearmouth, Sunderland, William Lumsden Byers, to Florence, daughter of Henry Overend Bowman, Esq., M.D.  
 PAGE-BAUTHEMELL.—On the 19th inst., at the parish church, Holmes, Westmoreland, David Page, M.D. Edin., eldest son of Dr. Page, Professor of Geology and Mineralogy in the University of Durham, to Mary, only daughter of John Rauthmell, Esq., of Brook House, Holmes.  
 ROGERS-FLOWER.—On the 20th inst., at St. Mary's, Lambeth, Hildyard Rogers, M.R.C.S., to Edith, second daughter of the late George Flower, M.R.C.S., of St. Martin's Road, Stockwell.  
 SEWELL-WILSON.—On the 18th inst., at Cliffe-at-Hoo Church, co. Kent, Frederick John Sewell, to Elizabeth Charlotte M'Sween, eldest daughter of the late Andrew Wilson, Deputy Inspector-General of Hospitals.  
 SMITH-TAYLOR.—On the 19th inst., at the Church of St. John the Evangelist, Taunton, Frederick John Smith, to Annie Eytton, second daughter of Thomas Taylor, M.D., late of Adelaide, S.A.  
 SWANZY-DEWHAM.—On the 19th inst., at 30 Merrion Square, Dublin, by the Rev. W. B. Kirkpatrick, D.D. assisted by the Rev. David M'Kee, Henry B. Swanzy, M.D., F.R.C.S.I., Upper Mount Street, Dublin, to Mary Knox, eldest daughter of John Denham, M.D.

#### Deaths.

DURHAM.—Late, at Sandford, co. Dublin, Andrew Durham, M.D., Deputy Inspector-General of Hospitals, aged 61.  
 HAYMAN.—On the 2nd August, at West Malling, Charles C. Hayman, M.D., aged 42.  
 MAULE.—On the 9th August, at Bath, John Templeman Maule, M.D., late Deputy Inspector-General of Hospitals, Madras Army, aged 73.

Established 1848.

#### PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.O.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S., &c. (King's Coll.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

Y 989. Unusual opportunity for a doubly-qualified gentleman with limited capital. A WELL-ESTABLISHED COUNTRY PRACTICE, without opposition, and yielding £420 a year. Appointments, £100. Patients chiefly middle-class. Convenient house, with large garden, meadow, and outbuildings. Rent, £25. Terms to meet the convenience of a *bona fide* purchaser.

Y 982. EXCELLENT FAMILY PRACTICE in a prosperous and pleasant town, containing 28,000 inhabitants. Midwifery fees, £1 ls. to £5 5s. Receipts average £1,700 a year. The work can be done with one horse. A most effective introduction can be given, and to a doubly-qualified gentleman accustomed to good society the Practice presents a safe and desirable investment.

Y 999. PARTNERSHIP, with SUCCESSION, in an old Cathedral Town. The present receipts average upwards of £700 a year. The locality is picturesque, and there is great scope for increase. Books open to full investigation to a suitable gentleman accustomed to good society. Easy terms of payment would be conceded.

Y 998. NON-DISPENSING PRACTICE in a prosperous town within 100 miles of London, and near the coast. The connection has been in the present hands for thirteen years, and is estimated to yield on an average about £700 a year. Expenses small. Patients good class. Ill-health the cause of retirement.

Z 9. In a fashionable watering place, an OLD ESTABLISHED FAMILY PRACTICE, the average receipts from which are between £1,000 and £1,200 a year. Midwifery having been lately declined, there is little obstetric practice, but there is scope for almost unlimited increase if this department were resumed. The house is large, very convenient, and very near the shore; it contains twenty-three rooms, with detached groom's house, stabling, &c. It can be purchased or rented. Ill-health and advancing age the cause of retirement. The premium would depend upon the introduction required; but no gentleman need negotiate unless he have at command at least £1000.

Y 8. PARTNERSHIP, with SUCCESSION in 3½ years. Present practice realises £600 a year, but is capable of immediate increase by the co-operation of an active gentleman. It is situate in a large town on the south coast, and there is scope for almost unlimited increase. There is a good house, with stabling, &c. Rent, £47. Expenses small. Premium £400, to include Succession to the whole.

Z 7. DEATH VACANCY. In a picturesque locality near the sea-side, the SUCCESSION to an OLD-ESTABLISHED PRACTICE is open for negotiation upon unusually easy terms. The average receipts have been about £1,300 a year, and there is little opposition. Patients very good middle-class. There is a convenient house, with stabling, &c., at a low rent. The greater part of the premium may be paid by instalments properly secured, the drugs, fixtures, &c., being taken at valuation. The whole connection can be safely transferred to a suitable gentleman.

## A Course of Lectures

ON THE

### NATURE AND TREATMENT OF DEFORMITIES OF THE HUMAN BODY,

DELIVERED IN THE MEATH HOSPITAL, DUBLIN, BY

LAMBERT H. ORMSBY,

Surgeon to the Hospital, and Demonstrator in the School of Surgery, Royal College of Surgeons in Ireland.

LECTURE VI.

DEFORMITIES OF PELVIS.

*The Great Importance of considering Deformities in this Region—The Situations—Dr. Robert Lee's Experience as to the Cause of Difficult Labour—The Doctrine of a certain Church as regards Craniotomy and Cæsarian Section—The Different Pelvimeters in Use, their Application, and their Non-Applicability in many Cases—The Degrees of Deformities—Classification—Causes of Pelvic Deformity: Treatment, Local, Constitutional, and Mechanical—Deformities of Sacrum and Coccyx: Treatment—Concluding Remarks.*

THE consideration of the deformities of this important region is ever of the greatest moment and interest to the obstetrician. Happy indeed would it be if every child-bearing woman was possessed with a "standard pelvis;" but, unfortunately, too often we are made conscious of the very serious, and sometimes fatal effects, that are produced to mother and offspring when deformity or abnormality is present.

These distortions are divided, for convenience, as they affect the *brim*, the *cavity*, and the *outlet* of the pelvis, singly or collectively. There are many causes prone to produce obstruction in parturition, and Dr. Robert Lee said that, in his experience, about 1-6th of all the cases of difficult parturition which occurred in London depended upon contraction of the pelvis from arrest of development or distortion, and in some cases the pelvis is so frightfully distorted that it is impossible to effect delivery at all;

but recourse to removing the child piecemeal, or by other recognised methods, must be practised. In a certain Church there is what I believe to be an erroneous doctrine, which is to the effect that it is against the tenets of their creed to sacrifice the life of the infant for the safety of the mother, and perform, when necessity requires, Cæsarian section instead of craniotomy. In some countries this unfortunate idea has been the means of causing many deaths of not only mothers, but also the infants of those who adhere most determinately to such a short-sighted doctrine.

Distortions of every description are met with in the pelvis, produced by various causes, and the diameters may be considerably below the "normal standard," and there are few osteological museums that do not present numerous examples of the frightfully distorted state the pelvis sometimes assumes.

Rickets and scrofula in early life, and mollities ossium in the middle or advanced periods of life are very frequent causes of deformity; some, indeed, are never detected until labour has actually commenced, which is effected by digital examination, or by contrivances made for the purpose of examining the pelvis at the brim. They are not much used in this country, and are more in vogue among our Continental brethren: the best known is Contoulli's pelvimeter, which resembles very much the rule with slide which is used by shoemakers for measuring the length of the foot; one end is introduced into the vagina until it reaches the promontory of the sacrum, the slide is moved until it is opposite the symphysis pubis, and then the antero-posterior diameter thus calculated. This may be applied and demonstrated very clearly in the lecture-theatre on a dry bony pelvis, but its value, to be of use, is only necessary in the lying-in chamber, and when labour has commenced and the soft parts are swollen and painful. The information thus elicited is found by experience to be of such a limited character that the finger seems to be the surest and most accurate method to be depended on.

There is another contrivance, which is the *compas d'épaisseurs*, or callipers of Baudelocque, and is intended to be applied externally to the woman's person. It consists of a compass, to the extremities of which are attached a curved arm, on the end of which there is a button; the

arms are divaricated so as to place one button on the symphysis pubis, just below the mons Veneris, the other button being placed posteriorly on the sacrum opposite the promontory. This, like the other instrument, is a very uncertain test as regards the true measurement, and in my opinion not to be depended on. When other bones of the body, especially those of the lower extremities, as observed by Naegele, are distorted by some constitutional disease, as rickets, mollities ossium, &c., and by the general appearance of the person, we may form a very fair reason for suspecting that the pelvis is also distorted; to what extent, however, can only be ascertained by digital examination, and, as I have before mentioned in another part of these lectures that one deformity nearly always predisposes to another, yet it must be borne in mind that because the spine may be greatly curved, the pelvis need not be necessarily affected, for it occasionally occurs that the pelvis is perfectly natural and of normal capacity when other parts are greatly distorted. Ramsbotham mentions such a case. The degrees of obstruction caused by distorted pelvis are classified in various ways by different authors. The brim, the cavity, the outlet may be the situation, as before-mentioned, and the obstruction is generally divided into three varieties—viz.:

1st. Those which will suffer the full-sized foetal head to pass entire.

2nd. Those through which delivery may be accomplished *per vias naturales* by means of premature labour, craniotomy, or mutilation of the foetus.

3rd. Those in which the degree of deformity is so extensive as to call for the Caesarian section, or the very early induction of abortion.

*Causes of Deformity of Pelvis.*—The various joints of the pelvis, like many other joints in the body, are liable to many forms of inflammation and their consequences—viz., ulceration, suppuration, and finally ankylosis, which occurs in the sacro-coccygeal joint, and is a most common obstruction in difficult labour in late marriages. Standing on one leg constantly, or one leg being longer than the other, tends to elevate one ilium, thereby placing the pelvis in an oblique position. Rickets, mollities ossium, constant sitting or standing in one position for a great length of time, excessive habitual horse exercise—Dr. Rigby mentions that frequent riding on horseback at an early age will produce contraction of the inferior outlet, even in the healthy pelvis, and that the females among American nations who over-indulge in this exercise bear few children, and are often three or four days in labour, owing to the contracted state of the pelvis.

Exostosis, tumours, fractures of the pelvis, caused by accident, falls, or otherwise, are also frequent causes of distortion.

*Treatment* depends greatly on the cause, and deformities in this situation do not interest us to the great extent that deformities do elsewhere, unless the matter of child-bearing is concerned, or unless it has attained such a great extent as to become apparent; for it must be borne in mind that very great deformity has often existed undetected until labour has actually set in; therefore the treatment seems in these cases to be more *preventive* than really curative, and when there is a constitutional tendency, great care should be observed, and active out-door exercise exchanged for the sedentary, &c.; constant change of position and attitude observed; if one leg is longer than the other, a thick leather sole applied to the boot until both legs are equal, good tonic medicine and nourishing food ordered, sea bathing. Treatment of these distortions by mechanical aid is a plan that ought occasionally be had recourse to, as some most ingenious instruments and appliances have been recommended from time to time. Where one ilium is considerably elevated, and the other being depressed, sitting on a sloping seat is a most admirable plan, the elevated ilium being placed opposite the inferior part of the inclined plane, and the depressed ilium opposite the upper part of the plane. Sitting in such a position for ten, fifteen, or twenty minutes at a time every day for a lengthened

period will have a wonderful effect in diminishing the obliquity and stimulating debilitated muscles into action.

Deformities of the sacrum and coccyx may be considered under this category, as both have a deforming influence on the pelvis; they not unfrequently are distorted, and produce (as can be seen by a visit to any anatomical museum), great deformity. Ankylosis of the coccyx with the sacrum is a most common occurrence after the middle period of life, particularly in women and in those who ride on horseback, also those who sit constantly, as dressmakers, milliners, &c.; it frequently causes most distressing labours; the bone is sometimes fractured, and this causes excruciating pain, particularly when the bowels are acting. This ankylosis may be met with as early as thirty-five, but mentioned by some authors as occurring later on in life; it frequently gives great trouble in the first confinement of a late marriage. Treatment very much the same as that of the pelvis, and generally more *preventive* than curative; and when the slightest predisposition is observed, everything should be adopted to prevent the deformity from increasing. As regards the treatment for pelvic deformity when labour has actually commenced, it is a matter that need not be much attended to at the time, as all attention, as a matter of course, will be directed to the happy and successful delivery of the foetus. Such treatment is entirely out of the scope of these lectures, and will be found at great length in works on obstetric medicine.

#### REMARKS ON THE USE AND ABUSE OF SPIRITS AND FERMENTED DRINKS IN ARMIES DURING WAR.

By Surgeon-General C. A. GORDON, M.D., C.B., &c.

(Continued from page 153.)

OUR Continental brethren observe, with regard to wine that it contains an agent (alcohol), which taken in excess becomes an absolute poison. It contains that agent, however, combined with other elements, especially nitrogen and carbon, in conditions which science is as yet unable to reproduce, but which render it a veritable aliment. It is observed also that populations which habitually use wines are not those in whom drunkenness, that curse of civilisation, prevails. Wine taken pure, says M. Morache, increases thirst instead of relieving it; but if diluted with water quenches thirst better than anything else; and such, I venture to assert, may be said in an especial manner of good sherry and iced soda-water on a hot day. Still quoting M. Morache, wine in moderation produces an impression of increased strength and muscular activity, it increases the functions of digestion. This arises partly from the effects of alcohol contained in it, but also from the introduction into the system of organic and mineral matters which act as aliments and as excitants of the nervous system. During the Prussian siege of Paris, in 1870-71, the good effects of a regular ration of wine were illustrated in a remarkable manner. In the course of that siege the daily allowance of food underwent a progressive decrease in quantity and quality, until after a time scarcely sufficient food was allowed to maintain life, and altogether insufficient to support the exertions demanded of those engaged in the defence. Throughout the whole period an allowance of wine was granted for each inhabitant, and I can speak from personal experience of the absolute craving felt for that beverage when food had become scarcest; famine, indeed, prevailed everywhere; still, famine fever was absent, a circumstance which has with every appearance of good foundation been attributed to the fact of wine being at all times issued to all classes of the population.

According to official regulations, the issue of certain beverages to the soldiers of the French army is authorised while they are employed on active service, but not

during times of peace, except on fête days, and formerly when the great annual inspection took place. Among those beverages are light wines, a quarter of a litre being sanctioned per man, at an expense to the State of 16,425,000*f.* per annum. (a) Among the other beverages are beer and cider in quantities of half a litre each, and eau de vie, of which the ration when granted is 1-32nd litre. During the hottest period of summer this spirit ration is granted for the purpose of "clarifying the water they drink," the distribution being made divisionally on the recommendation of a committee composed of the intendant, an army medical officer, and a civil practitioner. While on service, it is recommended in works on hygiene of the same army that a small quantity of spirits mixed with water shall be taken at night, especially if the nights are cold or humid. It is equally useful when bivouacking, or after forced marches, whenever the troops have been exposed to much rain, and in other circumstances in which it is necessary for the time being to set up the tone of the system; besides this, it is considered that a little spirits and water during hot weather conduce to digestion, being at the same time a wholesome beverage. Further, the regulations point out that undiluted spirits irritate the stomach and increase thirst, and that even in a diluted state they ought always to be taken during a meal, or with food. It is made a part of the duty of the medical officer to watch over the issue, and to see that spirits are diluted with the proper quantity of water—namely, eleven parts to one. Instead of pure spirits and water the following preparation is recommended for issue to the soldier—namely, 800 grammes of liquorice-root, four citrons, two litres of eau de vie, and twenty-two litres of water, the whole to be allowed to macerate during some hours, and supposed to serve as an allowance for eighty men for one day, at an expense of three centimes per head. This beverage is described as being particularly well suited for quenching thirst. According also to regulations, the eau de vie issued to the troops or sold to them in cabarets near the barracks must be the product of distillation of the grape, if it be possible to obtain it of that description. When from circumstances that is impossible, the intendants may issue spirits prepared from grain, juniper, or other natural products; but it must be of a strength equal to 47° of Guy Lussac's alcoholometer at 15° C. or 60° F. When wine is issued, the red is given in preference to the white; it is laid down that only those of good quality are to be given to the soldier, of a strength not less than 11 per cent. of spirit. It is also of some importance to mention in reference to recent discussions in this country in regard to sherry, that in France a special order prohibits the issue of *vins plâtres* to the troops. M. Morache (b) gives a reason for this objection. According to him, the alkaline phosphates and bitartrate of potash which exist in unplastered wine become through that process replaced by sulphates of that base, and in addition various salts become introduced by the process, especially chloride and sulphate of lime, the latter being soluble to a considerable extent in the wine. That issued to the troops is tested by means of chloride of barium.

Beer is considered, when taken in moderation, to be a veritable aliment by its alcohol, albuminised matters, and mineral salts. It probably acts as an antiscorbutic, but whenever indulged in or taken under unsuitable circumstances, it becomes directly injurious, chiefly by the lupuline contained in it. The strong beers of Strasbourg contain from 4 to 5 per cent. of alcohol, those of Germany from 3 to 4. Both descriptions are said to rapidly produce intoxication whenever indulged in, and further, are said, when freely persisted in, to destroy energy and courage, and to induce *brutishness*. The lighter kinds only are allowed to be sold to soldiers in France; but, unfortunately, the amount and nature of the beverages indulged in by the soldier of that country, like that of some others, depend more upon the primary means of the

individual than upon the regulations of his service. Intemperance is stated to have greatly increased in that army, especially in camps and quarters where the men have much time at their disposal. It is in an especial manner so among the old soldiers, and this circumstance forms one of the reasons adduced by General Trochu (a) against retaining men continuously in the ranks. He attributes this to the practice of issuing a daily ration of spirits to the men, a taste for "drink" being thus after a certain time established. In France, as elsewhere, the existence of the vice of drunkenness in the army is deeply deplored, and certain measures are adopted with a view to moderate it. Others are proposed, and among them it is noteworthy to find enumerated moral and religious instruction, utilising the spare time of the men, whether by work or by exercise, physical or intellectual. Strangely enough, however, it does not appear to be anywhere proposed to withdraw or prohibit the ration of spirits itself.

Throughout the winter of 1870-71 drunkenness prevailed to a great extent among the levies of National Guards raised for the defence of Paris, leading on the one hand, according to the belief of many, to military disaster, and on the other being, it was said, an important item among the circumstances that induced the high rate of mortality which prevailed towards the end of the siege. Vigorous attempts were made to check the prevalence of the vice. Organisations were established for the purpose of appealing to the moral sense of the men, and to induce them to bind themselves to total abstinence. The Council of Public Health issued a series of instructions with a view of impressing upon the troops the fallacy of the belief that the extensive use of spirits rendered them better able to withstand exposure to the severity of the season, and pointing out the greater risk of death from wounds in the intemperate than in the temperate. Much stress was laid upon the circumstance usually accepted as a fact, that in the War of Secession in America the use of spirits had been actually prohibited with the best results in regard to health and discipline among the troops; yet the Council of Health, so far from advocating the total prohibition of stimulants under all circumstances, expressed themselves thus: "After being on sentry in the cold and rain some warm soup, coffee, and tea with sugar, and to which a very small quantity of brandy or rum is added are the best kinds of drinks." It is to be observed that one of the most painful effects of the diminished supply of food in Paris was inability to maintain natural warmth; fuel had become next to unprocurable at the very time that the cold of winter was most intense; soup could only be had prepared from horseflesh, or from *stock* of even a still more objectionable nature, and really after a time tea and coffee, coffee and tea began to pall a little upon the palate; tea was dreadfully "filling," and as to coffee, the flavour seemed never to be out of our mouths. Under such circumstances, those of us whose principles were the most temperate were fain to indulge in a tumbler of hot spirits and water after turning into bed. It certainly restored the warmth of the body, and enabled us to enjoy a certain amount of comfortable sleep, which in the absence of the "night-cap" we could not have done, so painful was the sense of cold, however abundant the coverings we heaped over ourselves in bed.

With regard to the German forces during the Franco-Prussian war, I find that from the 6th of August, 1870—that is the date on which fighting began at the battle of Wœith—a ration of Brantwein, a spirit distilled from malt, was issued to them. This spirit was of a strength of 18° below proof; it was issued in the proportion of a sixth of a pint per man, mixed with an ounce of essence of bitter orange-peel, and drank without being further diluted, the Poles and East Prussians being credited with a remarkable "tolerance" of spirits. During the invasion of France the German soldiers were billeted upon the in-

(a) Morache, page 848.

(b) "Traité d'Hygiène Militaire," page 851-2.

(c) "L'Armée Française en 1867," page 86.

habitants, and this is the ration the latter were forced to supply to each of their guests—namely, 750 grammes of bread, 500 of meat, 250 of bacon, 30 of coffee, 60 of tobacco, 5 cigars, a demi-litre of wine, or a litre of beer, or a decilitre of brandy. Officers were supplied with cigars and *vin rouge*, both of superior quality. Here there are no indications of abstinence being practised among the Germans; nor is the scale shown by any means all that the unhappy French were forced to supply to the invaders. Every considerable town that lay in their road to Paris was “requisitioned” for supplies. Saverne may be taken as an example of what was thereby implied, the following list representing the quantities it had to furnish—namely, 10,000 loaves of bread of 3 kilos each, 60 bullocks of 250 kilos each, 8,000 kilos of rice, 1,250 kilos of roasted coffee, 750 of salt, 500 of tobacco, or 18,000 cigars, besides 750,000 kilos of *superior* cigars for officers, 10,000 litres of *vin ordinaire*, 3,000 of *vin rouge de qualité supérieure*, 2,000 litres of Burgundy, 200 bottles of champagne, 100 kilos of sugar, 25 of extract of meat, and full rations for the horses of the force entering the town. Everywhere tobacco, wines, and spirits were requisitioned according to a similar or even greater scale, although German physiologists might demonstrate scientifically that neither were necessary, nay, that they were all unnecessary, yet German staff officers continued their requisitions; German soldiers and officers indulged freely in them, regardless, no doubt, of *scientific* principles, and also of those principles which inculcate mercy and consideration for the poor and helpless everywhere.

Much has of late years been said and written anent the absolute prohibition against the issue of spirits by General Grant to the soldiers of the army of the Potomac. When one reads the instructions issued by Dr. Hammond for the preparation of a tonic of quinine to be issued as a prophylactic against illness in that army, I, for my own part, must be excused if, like my countrymen, “I hae my doots” as to what is meant by such absolute prohibition. The tonic in question is prepared according to the following receipt, and my readers will doubtless see for themselves wherein lies the difference between it and spirits: Half a barrel of whisky being drawn off into another cask, both were filled with a mixture of the bark of dogwood (*Cornus circinnata*) and wild cherry (*Cerasus scrotina*); after they had been dried in the sun, a few ounces of quinine were then added to each barrel, together with the dried peel of a dozen native oranges; of this mixture one or two ounces were given every morning and evening to each man, with the effect, it is stated, of lessening the relapses of fever. And so spirits were absolutely prohibited in the army of the Potomac!

The views entertained by American army surgeons in regard to the issue of spirits to the soldiers may readily be gathered from the work of Dr. Hamilton. (a) According to that work Dr. Mann speaks as follows: “My opinion long has been that ardent spirits are an unnecessary part of the ration; this allowance as part of a ration is not, however, the evil which demands a remedy, it is the abuse of spirits.” He further adds: “Sutlers, unrestrained as they frequently are, destroy more lives by these liquors than are lost by other causes to which soldiers are exposed, and so long as ardent spirits are permitted to be publicly sold in the vicinity of a cantonment these evils cannot be remedied by any restrictions under which sutlers may be placed.” These remarks are quite as applicable to our own army as to the American. It is not the ration of spirits of itself that effects the harm, it is the excess; and here in England all we have to do is to substitute the words “low public-houses” for “sutlers,” and the description is ours. At those periods of the revolutionary war when the army received no pay for their services, and possessed not the means to procure spirits, it was healthy, and it is added, “when the soldier is poor in money it is always the case that he abounds in health.” But that absolute prohibition is not intended of late years seems clear from special orders issued from Head

Quarters, Army of the Potomac, May 19th, 1862. That order declared that “upon the recommendation of the medical director an extra ration of one gill of whisky daily will be issued until further orders to every officer and soldier in this army, half to be served out in the morning and half in the evening.” How, therefore, it has become the fashion in this country to state that spirits were prohibited in that army I am unable to comprehend, except, as expressed upon the scroll in the hand of Shakespeare’s statue in Leicester Square—“There is no darkness but ignorance.” It is right to observe, however, that the order in question “was issued at a time when the troops had for several weeks been subjected to great hardships on long and fatiguing marches, in labour upon the trenches, in severe battles, in skirmishes and picket duty, in exposure to rains and malaria,” and when “sickness was prevailing to a large extent.” No wonder, then, that “by most of the army it was received as a boon, and by no commanding officer, so far as we are informed, was it refused.” (a) This extra allowance was subsequently withdrawn, but it does not appear that the men were deprived of the tonic already described. Dr. Hamilton questions, indeed, whether any real good followed the issue of the ration; indeed, he observes that “affections of the bowels were generally increased in severity and frequency by its use, while we never saw an example in which it had effected a cure.” No wonder, for who ever heard of whisky curing diseases of the bowels? Perhaps the true reason of the want of universal good effects is that given by Surgeon Price, (b) namely, that the ration was given without discrimination between those who need it and those who do not—“The men will be most likely to get the whisky ration when idle in camp; while on the march, when it might be claimed to be useful to the more feeble of the men, they will not have it; and at the end of a forced march the supply will be very certain not to be at hand.” Dr. Hamilton himself would under no circumstances whatever allow soldiers to have spirits. According to instructions published by the American Sanitary Commission, (c) “great care should be taken to guard against the excessive use of alcoholic drinks. It would be well for the young men in our services to make no use of these beverages except when they are prescribed for medicinal purposes.” (d) Again, “spirits should only be issued to the men after unusual exertion, fatigue, or exposure, and at the discretion of the surgeon. Those men who drink spirits habitually, or who commit excess in its use, are the first to fail when strength and endurance are required, and they are less likely to recover from wounds and injuries.” (e) By the same code of instructions, however, it is not alone spirits that are injurious when taken in excess: “Water should always be drunk in moderation, especially when the body is heated.” “Experience teaches the old soldier that the less he drinks (of water) when on a march the better, and that he suffers less in the end by controlling the desire to drink (water), however urgent.” (f) It thus appears that it is not alone against strong drinks that precautions are necessary—that water, even when undiluted with spirits, if taken in excess, is dreadfully dangerous. All things in moderation, at the proper time, and in their proper place.

#### REPORT ON SYPHILIS.

By C. R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.,  
Senior Physician to the Metropolitan Free Hospital.

DR. FOURNIER ON TERTIARY SYPHILIS (*continued*).

This forms the continuation of Dr. Alfred Fournier’s admirable lectures on tertiary syphilis, and of that part

which treats of the important lesions of the soft palate and pharynx of this formidable complaint. The notes are taken from a report by Dr. Pichard in the *Mouvement Medical* of the 18th July.

**Functional Disturbances.**—You remember how little functional disturbances were a marked feature at the period of formation and softening of the gummy tumour in the velum palati. They were so little so that the lesion was as if latent, and the patients at least scarcely disquieted themselves about it, and considered it as a simple sore throat of insignificant nature, so that the majority for the most part hesitated to consult a doctor for such a trifle.

Well, when the ulceration is accomplished, what is produced? If the ulceration limits itself to eating away the velum, attack it partially, without perforating it, or breaking it, the functional disturbances still remain but little in intensity—they remain what they were, with the exception of a slight addition of pain, a more or less marked augmentation in the difficulty of deglutition, and a notable increase in salivation. But the modification in the state of the symptoms is not striking; their intensity is simply a little greater.

If, on the other hand, the ulcer has perforated or divided the velum, then there takes place a truly visible change. Yesterday the disease was nothing, or almost nothing—it hardly disturbed the functions; to-day it is a profound disturbance, an intense disorder of two functions; two infirmities have come on at once, one of which is among the most annoying, the other one of the most disgusting. You shall judge for yourselves.

What is first of all singular in these disorders is their instantaneous appearance, their explosion as sudden as unexpected. They take place in one day or two.

What, then, are these functional disturbances? These are those which attend the division and perforation of the velum, whatever be otherwise the cause and origin of them. These disturbances, which you have already remarked, are two in number—1. Alteration of the voice; 2. Nasal reflux of the food, and especially of liquids.

1. **Alteration of the Voice.**—As soon as the lesion of the velum is accomplished the voice takes a nasal tone of a most disagreeable kind, becomes confused, and may even be no longer but with difficulty intelligible.

2. **Nasal Reflux.**—A portion of the food contained in the mouth escapes from the mouth and passes into the cavity of the nostrils to stay there or be rejected by the nostrils.

This reflux, rather rare and but little marked (generally at least) in the case of solid food, is more easily produced with liquid food or drinks, which, hardly taken into the mouth, partially return through the nose, and are thrown out by the nostrils. Constant in their production as regards phenomena symptomatic of rupture of the velum, these two functional disturbances are nevertheless very unequal from one patient to the other, according to the varying conditions.

Let us take two extreme cases to contrast them.

With a large perforation, and *à fortiori*, with an almost complete destruction, or complete destruction of the velum, these two disturbances of function attain their maximum of intensity. The voice is not only nasal, it takes on a very disagreeable tone, and, besides, is confused, the majority of the syllables are inarticulate, and often even the voice becomes so confused that it can scarcely be understood, and is almost unintelligible. Such is the case with a poor young married woman whom I am treating at this moment. She contracted syphilis from her husband at the early hours of her marriage, and was never treated, because she was ignorant of the disease she was affected with. Among other accidents she was affected with a gummy tumour of the palate, which has absolutely eaten away the whole velum, and which is not yet cicatrised. Her speech is so confused that I hardly comprehend her. Spite of all the attention I give to listen to her to diminish the grief she feels at not being under-

stood, I guess what she desires to say rather than I understand it. I hardly understand one word in ten.

In these same cases the disturbance of deglutition is excessive: foods of all kind penetrate into the nasal fossæ and remain there. If the solid foods are rather rarely rejected through the nostrils, it is not thus with the liquids, which flow back almost continually from her mouth and nostrils. The patients only avoid this double inconvenience by minute care, and by compelling themselves to eat slowly and watch the moment of deglutition, and by drinking little mouthfuls, laying the head back at the moment of swallowing, &c. Thanks to this kind of new education they impose on themselves, they come to be able to eat and drink well or ill; but they never, however, arrive at being able to conquer the functional disturbance which results from the absence or mutilation of the palate. A simple distraction of a moment, or a little hurry, suffice to produce the reflux. Here is what one of these patients lately writes:—"By force of education I have arrived at speaking, if not correctly; at any rate, at swallowing nearly like anyone else. I have scarcely any longer any difficulty in eating; but I am rather annoyed in swallowing. If nothing hurry me, if I am not absent-minded, all goes well; yet for all the world I would not dare to dine out, for I should fear evils for which I should blush. But if I am absent, if I am in a hurry to eat or drink, then my old infirmity comes upon me—thus, on coming home, I went into the railway station to take a glass of beer: I was swallowing it too quickly, thinking I was late; a part of the liquid returned in a gush through my nostrils."

Inversely, if the perforation of the velum is very slight, these same functional disturbances descend to their minimum of expression, and may even be wanting—at least they are extremely attenuated. The voice is hardly nasal in tone, solid foods are no longer regurgitated by the nasal fossæ, although liquids flow back, and even these only do so rarely and accidentally, or in a hardly appreciable manner.

Between these two extreme cases take all the intermediate terms as lesions and functional disturbances, and you will have in this way a picture of complete kind of what perforation or division of the palate can produce. It is not, however, the extent alone of the lesion of the velum which measures the intensity of the functional disturbances. This intensity depends on other conditions, all of which I cannot recount; but the principal appear to be the seat of the lesion, its form and age.

**Seat.**—The marginal ulcerations are much less influential for the production of such disturbances than central perforation. The destruction of the uvula, for instance, is quite inoffensive.

**Form.**—Perforations which are quite round are much more redoubtable with regard to disturbance of voice and deglutition than elongated perforations, or elliptical ones, &c.

**Age.**—The age of the lesion has also a marked importance. From the very first the reflux of drink is almost constant, whatever otherwise be the diameter of the perforation. This is due not only to the perforation, but also to the peripheral rigidity of the velum. Later on this reflux is infinitely less, which is above all due to the education of the patient in swallowing suitably in his now condition. It is useless to add that these attenuations of functional disturbances (especially in what concerns the voice) are only produced in cases of small or middle-sized perforation at most. These functional disturbances, on the contrary, persist if the perforation be extensive. They persist especially as far as the voice is concerned, which cannot be modified by education and surveillance as deglutition can.

The reflux of food by the nostrils and the alteration of the voice are the chief functional disturbances from perforation or division of the velum. But they are not the sole ones which these lesions cause. Some others remain for me to point out to you—namely, pain, salivation, and sometimes deafness,

Dulness of hearing and different disturbances of hearing (such as rumbling pains in the ear, &c.) sometimes accompany gummy tumours of the velum by propagation of the peripheral inflammation towards the Eustachian tubes. These are symptoms which we shall find repeated in treating of lesions of the pharynx.

Ptyalism is a symptom which is produced here, as it is in all wounds in the mouth; it presents nothing special.

Let us, then, only speak of the pain. You know how little painful the first and second stages of the lesion were. Pain comes on with the ulceration. This pain, in most cases, is either slight or medium (according to the extent of lesion). It consists in this: There is a feeling of constriction in the throat, constant, with slight smarting towards the isthmus faucium, with painful deglutition of saliva and food, and painful phonation. The patients are forced to choose their food. Often even (especially in the first period) they are reduced to nourish themselves on liquid food, soups, beef-tea, bread and milk, boiled eggs, &c. They speak little, and in a low voice; but in fine, they do not suffer much. This is the evidence given me by a patient who lost almost completely his palate in the campaign of 1871: "I did not suffer truly," he said, "I had a rather sore-throat, but that was all, and I attributed it to cold. If I had suffered, I would certainly have gone to the ambulance, but I was not obliged to leave my service;" and during this time this unfortunate man was losing his velum palati. There are cases, however, where the pain is very accentuated, although we cannot find the cause. Generally, then, it radiates towards the ear.

Such are the symptoms of gummy lesions of the velum palati.

Let us add, to complete the picture, the two negative tracts: 1. These lesions in general are not complicated by any enlargement of the glands. The absence of enlarged glands is the rule, the usual case; sometimes, however, it has been noticed that the perihyoidian glands were slightly swollen. 2. They do not awaken any general reaction. They never provoke any fever. All that is noticed in some cases, as regards disturbance of the health, is a certain degree of pallor and languor, caused less by the lesion directly than by the difficulty and insufficiency of the alimentation; and lastly, the moral condition of the patient on whom the onset of such unexpected and frightful symptoms is not without causing disquiet and great sorrow.

We have, gentlemen, studied one by one the successive stages of the affection: let us now put the disease together again, and study it as a whole. In a few words here is wherein it consists:—

The gummy tumour of the palate is composed originally of a pisiform or flattened tumour, solid, hard, without inflammation, which is developed in the thickness of the velum; we almost never are present at this initial stage of the disease. What we notice almost invariably among the first phenomena is a latter stage in which the affection displays itself in the form of diffused infiltration of the velum. The velum palati is then partly swollen, red, hard, thickened, and rigid. At this time there are few, or no functional disturbances—nothing more than some slight disturbances, and especially no pain. Then all at once the scene changes, as far as lesions and symptoms are concerned: Very rapid ulceration, attacking a more or less extensive part of the palate, perforating it, dividing it, destroying it in a more or less complete fashion, and that, I again repeat, with singular destructive activity, comparable in appearance to phagedæna; at the same time, sudden and unexpected explosion of serious accidents, two important functions (phonation and deglutition) injured in different degrees from one day to another, altered voice, nasal, and confused; nasal reflux of substances swallowed; pain more or less severe.

Such is the *résumé* of the affection which occupies us to-day.

Then, again, with regard to its progress, the disease is

divided naturally into two periods: 1st period. The future losses are being quietly prepared, without pain or any proportionate disturbance. 2nd period. The destruction, which is prepared all at once, is unmarked. And at the same time that these sudden lesions take place, intense disturbances take place in quite as unlooked-for a way. Insidiousness is then here the character which prevails, and about which the practitioner should be most on his guard, that which I have above all anxiously tried to bring out in relief and to make you rivet in your minds.

When the destruction we have just spoken of is accomplished, all is not over. Firstly, an ulcer remains on the parts destroyed. What is to become of this ulcer? If it were not treated, it would probably persist a long time, as we have noticed in several cases. Perhaps it also might extend. In any case, the experiment would be dangerous to make. All that I know is, that when treated, it generally is easily repaired, and quickly cicatrises. It cicatrises, you will understand, whilst leaving losses of substance almost always irreparable and proportional to the extent of the original gummy tumour. Often also, in certain conditions, it cicatrises only in a vicious way, and determines a series of phenomena known under the name of *pharyngeal atresia*, the fact we now speak of, and to which we shall again recur. Lastly, it is not rare for the cicatrix to take place only to become after a shorter or longer delay the seat of a new ulceration.

## INDIAN MEDICAL NOTES.—No. XXIII.

(FROM OUR SPECIAL CORRESPONDENT.)

SIMLA, July, 1874.

"ON LEAVE."

FALSTAFF, as melancholy as a gib-cat or a lugged bear, his voice lost by bawling anthems, vowed that if he grew great he would grow less, would shun sack, and live cleanly, as a nobleman should do: company—villanous company had been the spoiling of him. Badminton, riding-parties, dinners, dances—pleasuring, in fact, do not conduce to medical scribbling; thus it is some rarely put pen to paper, and never gratify their critical enemies by writing a book. Thanks to Dr. Bryden, the opportunity was afforded of gleanings much information if other attractions had not existed. Perhaps on return to sickness in the Plains the work at Meerut may, indeed, I fear *will*, supply ample materials, and health permitting, the best endeavour will be made to put before the reader the teachings of experience: for men may come and men may go; one will succeed, another fail in the combat with Indian diseases, many of which are as virulent and intractable as of old. There are still many things to be noted concerning the causes of sickness, and as the painter prepares the canvas, sketches the outline, then generally adds the figures, let me refer to Dr. Cutcliff's Report, which at last, after long seeking, comes under notice. In his investigations in the Meerut district in 1867 and 1868, about 140 towns and villages were closely examined to discover that sub-soil, soakage, lodgment, and stagnation of water, with insufficient drainage, aggravated malaria. One village would have a large sheet of surface-water, the soil light, sandy, porous, no quagmires, drinking-water good, canal irrigation partial, well-water not materially affected by the canal, village neat and comparatively comfortable, people healthy, robust, cheerful, and happy. Elsewhere would be large sheets of water, soil clayey, dark, sticky, retentive, quagmires, swamps, drinking-water bad, canal irrigation general, levels of well-water raised, villages dirty, untidy, people sickly, sullen, depressed, discontented, stagnant water, excessive vegetation, closely packed trees, shrubs, and grass preventing perfusion of air, dirt, filth, excreta, stinking ponds with filthy banks, or covered with green slime, oleaginous coating on surface of wells, enormous frogs floating therein, miserable

mud huts surrounded by bones, putrid carcasses, human ordure raked about by pariah dogs or loathsome swine, the men dull, stupid, cadaverous, lanky, often impotent, frequently with enlarged spleens, the women careworn, the children pot-bellied, no sounds of pleasure or activity heard in the bazaars, the only visitor the tax-collector. Such were some of the localities visited by Dr. Cutcliff. Where the canal-water was properly used for irrigation, not escaping or stagnating, where air was unimpeded the fever was less intense. Prisoners in gaols enjoyed immunity; railway officials at one place, and horse-tenders in another, before drains were cut in the lands, all suffered during the rains; their duties had to be performed by others, and medicines sent round in horse-buckets. Arsenic, atees, neem, chiretta did very little good compared to quinine; nor the native nostrum of slitting a live pigeon open through the breast so that the lateral halves flap on each side of the patient's head.

The fever so partial to water-courses and low swampy villages was oft remittent, associated with rheumatic pains, enlarged spleen, jaundice, dropsy, hepatitis, fatal diarrhoea, was either typhoid or malarial—let me add why not typho-malarial?—the type of fever to-day at work. The cattle suffered similarly, the large intestines and stomach, but not the excreta, containing red thread-worms half-an-inch long, the symptoms being listless lassitude, no appetite, stretched distended skin, rough coat, the loose folds about the throat swollen, oedematous pitting on pressure, aphthae of the mouth, diarrhoea, brown earthy motion, loose, offensive, mixed with a watery mucous fluid, sometimes bloody, the eyes dull, staring, naso-pharyngeal membranes dry. The weak were perfectly prostrate, the strong tottered with difficulty, yet the breathing was tranquil. Running on six days, the disease not considered contagious, terminated fatally by exhaustion or diarrhoea. In certain places the inhabitants developed gastro-enteric symptoms, painful abdominal distension, nausea, bilious vomiting, redness or softening of membranes lining alimentary canal, enlargement of intestinal glands, congestion of liver, engorgement of spleen. Meerut city was found above the average in cleanliness, brick-fields and kilns and much cultivation noticed, also new gardens by the gaol in stiff clay-soil required drainage. In the district, between November and March, 73 vaccinators, traversing 20,907 square miles, to protect against their wish a population nearly half that of England and Wales, do their best to modify a disease which scarcely any infant escapes. Births and deaths were reported by an illiterate sweeper to a native paymaster who lived eight miles off on a Dundreary system of totting on the fingers; and if the old ladies and female children did not come right, what matter? The cooking of statistics, an art of beautiful simplicity, is by no means a modern invention. Amongst the usual suggestions of drainage, sanitation, clearing of low jungle and high grass, opening of tree-forests, together with comments on crops, levels, streets, court-yards, cess-pits, Dr. Cutcliff recommended the free planting of chestnut-trees. Closing this interesting report, let me remind the reader that the author died just as his feet were on the ladder of success. Drs. Cunningham and Bryden are still working away, and though as yet I have not had the pleasure and privilege of meeting the former, his books and researches are and will be always eagerly demanded as the most valuable teaching of the day.

In a newspaper it is stated that arsenic, opium, aconite, dhatura, nux vomica, corrosive sublimate are freely used to poison men and beasts, and that for a pittance in the bazaar a pound of white arsenic, sufficient to poison 1,400 persons, may be openly purchased. Also at Bangalore, in 1873, no less than 2,083 cobras were destroyed in the presence of Dr. Nicholson, mostly in May and June. Elsewhere it is mentioned that the income from sweepings of latrines at Meerut formerly amounted to £50 a year. For any man who has the leisure it would be curious to compare the Indian diseases of to-day with those fatal in England long ago, when our kings drank hard, nobles lived in hovels and had neither vegetables, tubs, nor soap, and,

above all things, the comfort of tobacco. King James, taxing the latter said, if the devil came to dinner he should have a pig, a pole of ling and mustard, followed by a pipe of tobacco. Charles the First, a non-smoker, had in prison tobacco puffed in his face; and Oliver Cromwell, who trampled down the crops and raised the tax, was buried by soldiers puffing vigorously in derision. When England was a swamp, infested by wild beasts and robbers, there died of dysentery Prince Henry, son of Henry the Second, King John, Edward the First, Henry the Fifth, Cardinal Wolsey, Earls of Leicester and Essex. Fever killed the Earl of Gloucester, Henry the Eighth, Cardinal Pole, James the First, Oliver Cromwell, Charles the Second, a daughter of Charles the First, and Villiers, Duke of Buckingham. Amongst those illustrious in India, a reference to the standard inimitable writings of Sir John Kaye tells how Lord Cornwallis, thrice appointed Governor-General, died of dropsy, aggravated by bad food and worse water, on board ship; Sir John Malcolm, struck with paralysis, and Elphinstone, in green old age, died suddenly, both in England. Laurence, Neill, and Nicholson were shot; Burnes and Conolly butchered. After thirty-eight years' unbroken work under an Indian sun the seeds of malignant cancer commenced to torture Sir Charles Metcalfe—the ulcer of the cheek irritated by the climate of Jamaica; the agony of caustics, for instance, chloride of zinc, led to no good results—the right eye destroyed, the left useless, the jaw fixed, yet, in spite of pitiable pain, he continued unflinching at his work, ever cheerful, never complaining, fully sensible that Sir Benjamin Brodie and Mr. Pollock had exhausted human skill: a peerage came too late, for death relieved from suffering the first and last Lord Metcalfe. Just now universal sympathy is felt in India for that gallant soldier Sir Henry Tombs, and the earnest hope entertained of his restoration to health from a bed of sickness to wield again that good and trusty sword for merry England.

#### THE CORRELATION OF MEDICAL POOR RELIEF AND PUBLIC HEALTH ADMINISTRATION. (a)

By HENRY WILDBORE RUMSEY, M.D., T.C.D., F.R.C.S.E.

THE connection between the medical care of the poor and the public exercise of preventive medicine was traced, however imperfectly, by myself, in the second and fourth of my "Essays on State Medicine," and all subsequent events and discussions have seemed to confirm the principles which I then ventured to lay down and the practical conclusions which I drew from them.

Having shown that scientific inquiry is the indispensable basis to sanitary administration, I then mentioned that there were THREE classes of official agents necessary to the collection and compilation of the facts to be subjected to the higher processes of scientific analysis and induction—namely (1) The medical attendants of the sick poor, under the Poor Law; (2) Medical officers of health under the Public Health Act; (3) The registrars of births and deaths.

Of the last-mentioned I need say but little on this occasion, for the *status* of the department of vital statistics has never been seriously threatened, and the general register office is now brought fairly into co-operation with the central sanitary authority. Since the establishment of that department in 1837 it has undergone a succession of administrative amendments, another of which, making registration compulsory, has just received the sanction of the Legislature. The yet required adjustment of the local machinery of registration with that of medical relief and of disease prevention will be noticed hereafter.

I proceed at once to remark on the employment of the Destitution Medical Staff in health administration; and I would meet a preliminary difficulty, arising from the fact that a very large proportion of sickness among the

(a) Read at the Annual Meeting of the Bristol Medical Association, August, 1874.

poorer classes, and in towns by far the largest proportion, does not come under the care of the district medical officers under the Poor Law. This, however, is an argument rather against the fragmentary and irregular, yet complex character of our various social arrangements for medical relief, than against employing the legally appointed medical visitors of districts as sanitary officers. It is an argument for charity organisation, and for bringing all institutions for the treatment of the sick poor, whether legal, charitable, or provident, under a combined system—a reform for which we must look to the future.

Whenever effected, so far from checking or depressing charitable and voluntary efforts, some sort of consolidation might so regulate, extend, and improve them as to diminish materially the present cost of relief under the Poor Law.

Within ten years, however, after the introduction of the new Poor-law arrangements, the abuses of the system were so flagrant that it became a question whether it were not advisable that all medical action, even in the mere relief of disease, should be removed from the administration of the destitution authorities, and whether those authorities might not be advantageously restricted to the provision of relief in money or kind, leaving the higher question of the cure and prevention of disease to purely sanitary authorities. I believe that Mr. Ceely and I were the first to bring this question formally before a committee of the House of Commons in 1844. That very able and philosophical statesman, the late Sir G. Cornewall Lewis, though not advising the immediate adoption of our proposals, admitted the reasonableness of our principle and the possibility of working it, while he used it as an argument against what has been attempted by inferior men since his time—viz., the constituting a medical department under the Poor-law Board. Although we were defeated in that effort, its principle has never been lost sight of; but the firm hold which forty years of Poor-law administration has given to a medical system, wrong in its foundation, renders the practical application of our theory a task of much greater difficulty now than it would have been when first laid before Parliament.

Here we are, then, saddled hopelessly with the Poor-law Board as masters of the position. The change of name into Local Government Board has not altered their nature. The building of the new administration of sanitary law upon the foundation of the old destitution department was from the first a doubtful expedient, and it has proved to be a fearful, if not an irretrievable mistake. The natural (and to some extent necessary) connection between destitution and sickness, and measures for their relief and prevention, by no means rendered it necessary that the Poor-law Board should be placed at the head of public health administration. The so placing that Board is a striking instance of what Matthew Arnold called the "Philistinism," which prevails in our social and political institutions, the coarse *ungeist* which stifles, corrupts, and debases our public measures.

But the thing was done because it seemed so easy. *Facilis descensus Averni, sed revocare gradum superusque evadere ad auras. Hoc opus, hic labor est.*

The question practically now becomes this: Is it possible to infuse into public administration, even under this Philistine board, a higher, a more free and noble spirit, by allotting to the physical sciences and to their exponents in the medical, chemical, and engineering professions a more influential and independent position? Is it possible to liberate those professions from the tyranny of the legal and official traditions—the red-tape bondage—of Gwydyr House? In reply, I say that we must begin with the basis of the Civil Medical Service, that numerous official body to which is committed the care of the sick poor in districts and public institutions.

The custom, now universally established by law, of assigning fixed salaries to the medical attendants of the poor is in reality an obvious recognition of the sanitary or preventive character of their office, otherwise they

would be paid merely for the sickness they relieve, and would have no material interest in preventing disease.

A full record of the sickness and accidents relieved at the public expense would therefore be the first element of a public registration of disease, applying equally to epidemic visitations and to sporadic attacks, and specifying the local conditions, the personal relations, and the topographical and physical circumstances connected with the loss of health.

The machinery for such a registration (as far at least as the poorer classes are concerned) is at hand, and always available; hitherto it has not been fairly utilised in Great Britain; but in Ireland, under the Medical Charities Act, the records of disease have long proved a most valuable aid to public administration. The corps of medical officers in England only requires to be placed in a similar position to that which it occupied in Ireland under a public dispensary organisation with sanitary authorities.

I hardly need occupy your time by suggesting those particular modifications and amendments in the periodical returns of the union medical officers which would fit them for the purposes of scientific registration without diminishing their direct utility in affairs of local management.

The honoured names of Liddle, Dundas, Thomson, Ballard, Richardson, Kansome, Philipson, Lewis, and many others will occur to those present as authorities on the subject, who from time to time have shown how the crude lists of the sick made by the union medical officers might be corrected, amplified, extended, and completed in readiness for the next stage in the process—namely, revision and analysis in the first place by chief officers of health, and finally, by the medical department of the central authority.

The same forms in an extended registration might apply as well to dispensaries and other public institutions, including mutual assurance societies, as to the district medical officers. In the last of a series of papers on this matter which I published in our journal for March, 1872, I ventured to enumerate the several particulars to be returned and the methods of entry, and to this I beg to refer my hearers.

I now proceed to say a few words on the *value* of the union medical officers as sanitary inquirers of the first instance. Testimony has been borne to that value by many eminent persons of different opinions in other matters—for instance, Mr. Chadwick himself, in the General Sanitary Report of 1842; numerous well-informed witnesses before the Parliamentary Committee of 1844; Mr. Simon, on several occasions, especially in his Report of 1849 to the Civil authorities of London; and the Rev. C. Kingsley, and others before the Parliamentary Committee of 1854, all showed how easily and properly the officer appointed to attend the poor might inquire into and report on the facts concerning the origin and propagation of disease among those committed to his charge; how advantageously he might act as the health adviser of the poor; how well-informed he must necessarily be respecting the locality of their dwellings, the condition of their apartments, their food supply, the physical management of their children, their nursing in sickness, and the effects of their occupations.

In this view of the case the sanitary qualification of the union medical officer becomes a question of vital importance. In Ireland an excellent opportunity for complete preparation for official duties is ensured by a regulation preventing the appointment of any medical officer to a dispensary under the age of 23 years, thus affording to the candidate two years for further study or for practical work under supervision, as assistant to a dispensary officer or house-surgeon in a hospital, after obtaining his licence to practise.

For such reasons many of us desire to see a special qualification required of all public medical officers of whatever class. There is no reform which would so certainly promote the greater efficiency or raise the status

and remuneration of the union medical officer as the possession of a special qualification in addition to the ordinary licence.

The mere inspector of nuisances, as he is called, must be a comparatively useless person, unless acting in official concert with a well-qualified medical officer. I assert unhesitatingly that the mode of regulating the joint and separate action of these two classes of officers (medical officers and nuisance officers) deserves a much more careful consideration than has been hitherto given to it by the central authority.

Some sort of domiciliary visitation for hortatory purposes, when possible, would make the dispensary medical officers missionaries of health in their respective districts; and in this noble calling they ought to be aided by a well-instructed and efficient body of *nurses*, such as recent philanthropic efforts lead us to hope may ere long be at work in most populous districts.

Again, it has been often a question whether the dispensary medical officer ought not also to be, *ex officio*, the public vaccinator of his district.

I am aware that the tendency of official inspection has been to separate vaccination on the one hand from preventive medicine, to which it certainly belongs, and on the other hand, from medical relief, with which in execution it is most conveniently connected, and to make the public vaccinator an isolated special officer, acting for the most part in a larger district than that generally committed to the union medical officer, and at all events without reference to the duties of medical or sanitary visitation—one alleged reason for this course being that the amount of population required to maintain an effective succession of vaccine virus may be larger than that ordinarily contained in a medical relief district.

But whatever may be the theoretical advantage of a somewhat larger area for vaccination, I believe that a diminution in the number of public vaccinators has not seldom been felt to be a serious obstruction and hindrance to punctual and prompt vaccination.

In the opinion of most who call for a general revision and adjustment of *areas*, the districts for medical relief ought to be either identical with, or divisions of, districts for the registration of births and deaths, public vaccination, house inspection, and minor sanitary reports. With the increase of population the difficulty raised by the too great limitation of vaccination districts will naturally diminish.

I am well aware that no such unification as we propose for the minor districts with rectified boundaries could be suddenly made; but I am satisfied that the required changes might be gradually and judiciously effected with much advantage to all the purposes of local administration, and with great saving of labour to the higher authorities. This is a reform of immense importance to the public welfare and convenience, and it ought to be vigorously supported by the medical profession; and it is also justified by the system established and at work in Ireland.

Those who know anything of my labours on the health officer question need not to be informed that I have long and consistently urged the great importance of those objects which are to be attained only by the employment of a higher order of medical officers of health over county combinations of districts as superintendents debarred from private practice.

But I always advised that they should be systematically aided by the great body of the medical attendants on the poor, acting as deputies. This condition has been distinctly supported by the joint committee of this and the social science associations.

Now, supposing that there are somewhat more than 3,000 union medical officers, and that about 100 superintendents are required for England and Wales, the average number of the union officers acting with and supported by each superintending officer might be more than 30. In my judgment it is very important that vacancies occurring among superintendents should be filled up by

the union medical staff, some of whom in each combination of districts would almost certainly have distinguished themselves by meritorious services, and would be duly prepared both by preliminary studies and by special experience for the inspecting duties of the larger sphere. On this scheme of organisation, not at present sanctioned by Government, there would be added to the ordinary motives for excellent performance of duty an honourable desire for promotion to the superior grade, encouraging self-improvement in special knowledge and a pursuit of science concurrent with the pursuit of duty.

In the legislative project which ended in the Public Health Act of 1872 the Royal Sanitary Commission made a very serious mistake in one direction; a considerable portion of the sanitary party made, in my humble opinion, an equally great mistake in another. The former pointed out the union medical officers, without any improvement in their *status* or qualification, as the proper sole officers of health in *rural* districts for reasons which merely justify their appointment as deputies; the latter objected to their being employed at all as officers of health, partly because they were not sufficiently independent in their professional position, and partly because many of them did not possess sufficiently high qualifications for the more difficult duties of the office.

The Local Government Board, unable to perceive the true solution of the difficulty, and rejecting medical counsel, sanctioned one defective plan here, another defective plan there. Those who wish to enjoy a trenchant, racy, and truthful *exposé* of the doings of the Local Government Board under Mr. Stansfeld should read Mr. Brudenell Carter's able address to the London Medical Society, on "The Waste of Life by Preventable Disease." (a) Suffice it now to say that in many districts of the kingdom we see the union medical officers acting alone in their respective districts, without in formation from the medical residents, and without performing the higher functions of comparison and analysis of facts, or drawing general conclusions as to causes and prevalence of disease, or instituting proceedings against the more influential factors of those causes; in other districts one of their own number is selected to act not only in his own original district, but in those of his neighbouring colleagues, who very naturally resent the intrusion; in other districts again, private practitioners out of office, yet rivals in practice, are appointed; while elsewhere certain large, irregular, and ill-formed combinations of districts are superintended without local aid by skilled experts debarred from private practice.

There is, however, a modification of this last plan which deserves candid consideration—viz., the appointment of consulting physicians or surgeons in hospital practice for special inquiries and inspections, for each of which a distinct fee might be paid, the ordinary duties of health officer being left to the local officers.

The various arrangements admit of very different relations with the inspectors of nuisances, and none of them as yet provide for systematic co-operation in the registration of sickness and sanitary inquiry.

But, if the Sanitary Commission and the Local Government Board had perceived that the proper sanitary functions of the union medical officers, though distinct, were yet quite reconcilable with the proper sanitary functions of superintending officers of health, and that the two official classes *must* act in every district, the Public Health Act would not have proved a failure in the medical department of its administration; the facts of disease and death would have been duly recorded and returned by the registrars and by the dispensary officers and vaccinators, the careful visitation of dwellings with preventive advice to their inmates would have been conveniently accomplished, the statistical returns of the medical officers of health, "being based on an uniform system," would have been full and accurate, while the facts recorded would have been analysed, grouped, and,

if necessary, verified by the superintending officer, his summaries and conclusions being reported to the authorities, whether central, combined, or local.

I cannot avoid protesting in this place against the course adopted by the Central Board (*a*) in recommending that the crude, incomplete, and uncorrected weekly relief returns made by the union medical officers should be handed over to the clerks of unions to be copied for the use of the officers of health without revision or explanation, or any pretence of remuneration to the original contributors, a course both unjust to the latter and delusive to the public.

In conclusion I must remind my readers that the greatest obstacle to correct sanitary administration has been the absurd statutory distinction between *urban* and *rural* districts and authorities, a distinction which was at once shown by our joint committee to be indefensible and unwarrantable, and which has caused most of the anomalies and difficulties encountered in the attempt to carry out the Public Health Act, a distinction which, I also regret to add, is clung to with a desperate and stolid tenacity by the present Government and its legal advisers, and by which they have succeeded in spoiling the sanitary measures of the late session for both England and Ireland.

### REPORT ON PHYSIOLOGY, MATERIA MEDICA, AND THE PRACTICE OF MEDICINE. (*b*)

By N. S. DAVIS, M.D.

PERHAPS the chief improvements or additions to our knowledge in the department of physiology during the year ending April 1, 1874, are such as relate to the functions of the brain and nervous system. The experiments of Fritsch and Thitzig, Nothnagel, Fourney, Ferrier, Dupuy, Carville, Bartholow, and others, for the purpose of determining more definitely the functions of particular parts of the brain, have attracted much attention. The novel methods adopted by these experimenters, consisting in some instances in the injection of distinctive substances, coloured with aniline, into the substance of the brain; and in others in the application of electric and galvanic action to limited portions of the cerebral hemispheres, and the striking results that followed, were thought by many to have brought a new era in the development of cerebral physiology, and to have overthrown many of the opinions hitherto regarded as well founded. Up to the time of these recent experiments it was supposed that the grey matter of the cerebral periphery, being the seat of mental perception, was not amenable to direct excitation by stimuli. But when Ferrier laid bare the surface of the convolutions and by applying his blunt electrodes, induced with readiness and apparent uniformity certain muscular movements, according to the convolutions touched, it appeared to demonstrate not only sensibility of the cerebral surface to stimuli, but also the special localisation therein of motor functions. By the subsequent investigations of Dupuy, as detailed in his inaugural thesis, it is shown that the faradic currents used by Ferrier could not be restricted to the peripheric layer of the brain, but they readily penetrated to the striated matter and central ganglia, and therefore produced their effect on muscular movements by direct excitation of these deeper seated parts. M. Carville, in repeating the same methods of investigation, more especially with the animals experimented on under the influence of anæsthetics, obtained results confirming the views of Dupuy. Very recently Dr. Bartholow, of Cincinnati, availed himself of an oppor-

tunity to perform a limited number of experiments on the brain of a patient, a large part of whose skull had been removed by disease in such a manner as to leave a considerable extent of cerebral surface bare, including portions of both hemispheres.

The mode of experimenting differed from that of Ferrier, chiefly in the use of fine needle electrodes penetrating the brain substance, instead of blunt ones resting on its surface. The results in producing muscular movements corresponded closely with those obtained by Ferrier on animals. And when during the third experiment the faradic current was rendered more intense, decided epileptiform convulsions ensued. While the results of these few experiments on the human brain correspond closely with those obtained by Ferrier, yet they are still more amenable to the objections made by Dupuy and Carville, because in making a subsequent post-mortem examination Dr. Bartholow found his needle electrodes had penetrated from one to one and a half inches into the cerebral substance. The whole history of experimentation involving the injury or mutilation of animals, for determining the functions of any part of the nervous system, shows that conclusions must be drawn from them with great caution. From a careful review of all these recent and highly interesting experiments their combined results appear to confirm the previous views concerning the functions of different portions of the brain, instead of overthrowing them. And if they have added anything to our physiological and anatomical knowledge it is in indicating more definitely the exact points of localities in the periphery, where the striated fibres forming the medium of communication between the central ganglia—as the corpora striata and optic thalami—and the grey matter of the convolutions touch the latter.

We had regarded these results of previous physiological experiments in connection with many pathological phenomena as sufficient to indicate clearly a primary centre for ordinary sensation in the optic thalami, to which impressions from all points of the body are transmitted by one set of nerve filaments, and from which they are transmitted to some point in the periphery by some of the white fibres intervening between these bodies and the grey matter of the convolutions, when the impressions are mentally recognised, and the resulting volition is sent from the same part by another set of white fibres, first to the central ganglia represented by the corpora striata, and thence to whatever set of muscles are required to obey the mandate of volition. Instead of indicating any new functions in the convolutions, or spinal organs of muscular sense, the recent experiments have simply indicated more directly the particular convolutions in contact with the conducting fibres communicating through the common centre with particular sets of muscles.

The observations of Dr. Eichorst (see *Virchow's Archiv.*) on the degeneration and regeneration of cut and injured nerves, are interesting and important. They were made on the nerves of rabbits, and appeared to establish the fact that cut and injured nerves first exhibit an accumulation of granular matter, increasing the bulk which appears to arise from a breaking up or degeneration of the medullary matter of nerve. The sheath, of Schwann, and the perineurium become swollen from serous transudation, while the axis cylinders remain but little changed. During the second week these exudative and degenerative changes gradually disappear, and the process of regeneration becomes visible in the form of delicate and slender threads running into and extending from the injured end of the nerve. The reparative action is observable at the end of the second week, and continues several weeks before it becomes complete. Dr. Eichorst made no observations in regard to the time required for the nerve function to be restored. But from the slowness of the reparative process, as well as from other recently observed facts, it is rendered probable that those cases of apparent speedy restoration of function after injury or excision of nerves reported by surgeons have been instances in which the parts received nerves from other sources.

(*a*) See circular letter signed "J. Lambert," and dated March 23rd ult.

(*b*) Read before the American Medical Association, and referred to in a former number.

While I would not discourage investigations in any direction, or in any degree undervalue the importance of a correct physiology of the nervous structures entering into the human body, yet I am strongly impressed with the idea that we are attributing too much to nerve influence, and too little to the influence of properties inherent in all living structures. We have come near to the standpoint of referring all impressions, healthy and morbid, to a primary reception by some part of the nervous system, and as a consequence, of regarding all vital actions as in some way dependent on nervous influence. In this we are confounding nerve sensibility and nerve force with properties that are inherent in living organic matter, and are as clearly appreciable in the primary germinal cell, or granule of bioplasm, as in the most highly organised nerve structure. I do not allude to vitality or the abstract principles of life, for it is doubtless beyond human comprehension. Imparted primarily by the Creator to matter in certain modes of combination, and perpetuated by parent to offspring throughout the whole domain of organic nature, both vegetable and animal, it stands in its relation to the human mind as an ultimate fact, incapable of further analysis or explanation.

But when matter is thus endowed with vitality it possesses certain properties that can be studied and comprehended as readily as we study the properties of inorganic matter. It is as easy to demonstrate that the germinal cell of the ovum or the acorn possesses a susceptibility to the presence of certain exterior agents, as heat, moisture, electricity, and a peculiar affinity by which it elects and combines with certain atoms of matter and rejects others, thereby affecting determinate changes that we call growth, as it is to demonstrate that an acid will unite with a base, or that the presence of a second acid will cause the rejection of the first and the formation of a new compound. Susceptibility and vital affinity are properties common to all living organic matter, whether in the primary germinal specks of a bioplasm or in the most complex structures of the human body. And they exert a controlling influence in all that relate to molecular changes in assimilation, nutrition, disintegration, secretion, and, as a consequence, in the evolution of caloric. These properties are capable of being modified or acted upon directly by all those pervading forces, sometimes styled imponderable agents, such as electricity, heat, light, &c., and by the presence of many alimentary and medicinal agents. They are in no sense derived from the nervous structures, and can be modified only indirectly by nerve influence. Every system of physiology which does not recognise these elementary properties of all living matter as distinctly as it does the special functions of each organised structure will be found defective. Not only will it be defective as a branch of science, but as the basis or point of departure for the study of pathology, it will continue to involve us in doubt, obscurity, and false conclusions.

**Materia Medica.**—The past year has not been made notable by the discovery of any new and valuable article of the materia medica, or by new applications of old remedies of such importance as to be worthy of special mention. What we most need, however, in this department, is not the addition of new articles or new applications of old ones, but a more complete knowledge of the composition and properties, with a more exact appreciation of the *modus operandi* of such as are already on the official list. The progress of organic and analytical chemistry, and its application to the investigation of the composition and properties of medical agents, is constantly separating out the active principles and presenting them for use in more convenient and reliable forms, but most of our methods of testing the effects of medicines on the various functions of the human body are extremely defective. So true is this that the most diverse opinions still exist concerning the action of many of the oldest and most frequently used articles of the materia medica. And not a few of them—like opium, quinine, alcohol—are commonly regarded as capable of exerting directly opposite effects by simply altering the dose. That is, we are told that in small doses

they are stimulant or tonic, and in large doses sedative or narcotic, but at what point in the progress of increasing the dose the action becomes reversed, no one appears able to point out with exactness. Perhaps in no other department of medicine do we find opinions and conclusions derived from investigations so partial or incomplete; and the adherence to names and classifications involve so much confusion. It is to this condition of our materia medica that we owe many of these apparently contradictory modes of practice, which have done much either to create scepticism, both in and out of the profession, or to fasten the theory that the type and character of diseases change with the cycles of time. The idea that the special type and character of diseases have undergone marked changes, and are far less active or sthenic now than in the earlier part of the present century, has become very general both in and out of the profession. And this is alleged as a reason for the change in practice from depletion and antiphlogistics to nourishment and so-called stimulants. But if we analyse more closely the development of opinions and modes of thought, as presented in the medical literature of the last half century, we shall be forced to the acknowledgment that the idea of change in the character of diseases has followed rather than preceded the changes in the modes of practice, and that it really has no other appreciable facts on which to rest. In other words, it will be found to have been a simple theoretic idea, suggested to avoid the difficulty and scepticism arising from such various and apparently contradictory modes of practice.

We say *apparently contradictory*, for it is not certain that a more careful review of the *modus operandi* of the remedial agents used would not show the most diverse in appearance to have really reached the same end by different routes. For example, on the assumption of the chronic physiologists that alcohol is respiratory food, acting as a stimulant to the organic functions and sustaining the temperature of the body, nothing could appear more opposite than to treat one case of fever or acute disease with arterial sedatives, evacuates and alteratives, and another case of the same disease with alcoholic liquids and nourishment. But when we turn from the theoretical assumption to the results of positive experimentation we find the ingestion of alcohol to be followed by a reduction of temperature, a retarding of capillary circulation and molecular change, and a diminution of nerve sensibility. In other words, we find the *assumed* stimulant to be a positive and universal *sedative* to organic and molecular changes and anæsthetic to nerve sensibility.

Hence the practitioner who plies his patient freely with wine, whisky or brandy, is as certainly holding him under the influence of a powerful sedative as was his ancestor who bled and physicked, or his contemporary who gave veratrum and alteratives; and we need resort to no supposable change in the type of disease to understand why all, if wielding their weapons with equal skill, arrive at very similar results. As already intimated, there is no other department of medicine that so urgently needs a thoroughly critical and experimental revision as our materia medica. The work should be carefully planned and persistently pursued until the erroneous phraseology is corrected, and the mass of speculations and mere assumptions are replaced with positively observed facts.

The pendulum of professional opinion and practice has swung from one extreme to another with almost as much regularity and certainty as if moved by the force of gravity. During the first half of the present century professional practice had reached the extreme of depletion and evacuates, when, checked by its own abuses, the return wave carried us in the short space of three decades first to conservatism or expectancy, and then to full stuffing and so-called stimulation, until wine, brandy, and indiscriminate nourishment were made the instruments of abuses no less injurious to the human family than blood-letting and evacuates in their palmiest days. This last swing of the professional pendulum has just reached its widest divergence from the perpendicular, and one of the most grati-

fying evidences of progress in practical medicine the past year consists in the plain indication to be seen in various quarters, that the pendulum has fairly commenced its return motion. The constantly increasing importance attached to fresh air, pure water, and frequently ablutions in the sick-room; the more careful adjustment of the quantity and quality of food to the capacity of the digestive organs for acting on it; the rapidly increasing condemnation of the indiscriminate use of alcoholic and other anæsthetic and narcotic agents; the occasional unsheathing of the long neglected lancet, with here and there a bold, outspoken advocacy of its judicious use; and above all, the better appreciation of the fact that a retardation of tissue, metamorphosis and elimination, is by no means equivalent to assimilation and nutrition, either in health or disease, are marks of a genuine progress, that can be easily recognised in the literature of practical medicine during the past year. And happy would it be, both for the profession and the public, if the return wave of thought, investigation and practice, now fairly begun, could be so guided by a higher mental discipline, the adoption of more patient and complete methods of observation, and the adherence to a more rational induction, as to turn it steadily upward at the true meridian line, instead of allowing it to roll steadily on until it again breaks upon the reefs and shoals of its own excesses. But we see no good reason for hoping for such a result. On the contrary, evidences of the same tendency to extremes and hasty generalisations are as visible in the field of practice to-day as at any former period. Very recently attention was directed anew to the importance of noting the variations of temperature in diseases, and straightway there appear diagrams marking the variation of temperature in the progress of diseases with as much apparent fixedness and certainty as the thermometric lines are drawn over the topographical map of a continent, and the practitioner looks upon his pocket thermometer as his chief instrument in diagnosis and prognosis. That temperature, if studied in close, careful connection with the co-existing indications of the state of nutrition, disintegration and elimination, is of great importance in a clinical aspect, is certainly true. It was the subject of my inaugural thesis in January, 1837. It was again the subject of a careful series of investigations by me, more especially in relation to certain kinds of food and drink, in 1850, the results of which were embodied in a paper read to this association in May, 1851, and published in the *North-Western Medical and Surgical Journal* for that year. Those investigations fully disclosed the important fact that the temperature of the body varied from  $1^{\circ}$  to  $2^{\circ}$  F. with each ordinary meal, invariably rising during the active period of digestion and then gradually declining until the next ingestion of food—thereby establishing precisely the same facts, that were again proved experimentally by Dr. E. C. Buckingham, of Boston, as published in the *Boston Medical and Surgical Journal* for January 1, 1874. It was in the same paper, read to this association in 1851, that the first direct experimental proof was given of the power of alcohol when in the human system to directly reduce its temperature. That the temperature of a body is altered by every change of its molecules, being increased as these become more compact or dense, is a well-known law of physics. As a rule those processes by which new materials are digested, assimilated and added to the tissues, evolve caloric or heat; while those by which the cells and atoms of the tissues re-dissolved, eliminated through the skin, lungs and kidneys, absorb or render the sensible heat latent, and therefore reduce the temperature.

When these adverse processes balance each other the ordinary standard of temperature is maintained, subject to such daily variations as accompany the active stages of digestion. Thence it is plain that a given degree of temperature in any stage of disease is a simple physical fact, the correct interpretation of which will depend entirely on the careful noting of the coincident state of the processes of ingestion and elimination. Just as the dullness perceptible on percussion denotes the simple physi-

cal fact of increased density, while the question whether such density depends upon tubercular deposits, hepatization, or pleuritic effusion, will depend altogether upon the history of the case and the coincident facts. If we use our clinical thermometer for the same purpose that we use the instrument for percussion and auscultation, that is, for the establishment of a physical fact to be interpreted by a careful appreciation of preceding and accompanying phenomena, it will be of great value. But if we endeavour to make its markings into arbitrary rules to guide our practice, as has already been too hastily attempted, it will lead us into mischievous errors at every step.

Another striking exemplification of the fact that our own day is as prolific of partial observations and hasty inferences as any that have gone by is found in the application of the microscope to the study of etiology and pathology.

Through its prolific revelations one army after another of poisonous germs are found preying upon the human race, until not only the air, earth, and water, but even the blood and the bowels literally swarm with them. From syphilis to cholera, and from them to cancer we have little else but microscopic germs enumerated as essential causes of disease. Dr. A., in some part of Europe, announces that he has discovered in the dejections of cholera patients certain germs, which by diligent cultivation multiply and develop rapidly, and a large part of the medical world at once leap to the conclusion that these are the veritable cause of that dire disease, and instead of patiently extending observations to ascertain whether the same germs are not to be found in the serous discharges from mucous surfaces, in any form of disease, after exposure to atmospheric air, they immediately give loose rein to imagination for the purpose of explaining how these extraordinary germs, hatched on the banks of the Ganges, could be propagated and distributed around the globe.

For this purpose they are made to travel with caravans, sail on ships, ride on railroads; and where there is neither caravan, ship, railroad, nor canal, they are made to percolate through the soil, receiving reinforcements now and then from some luckless wight perambulating the country with *cholérine*, and dropping his dejections just in the right place to supply the needed link in the chain of connection. But, just as we have our maps lithographed, our literature filled with satisfactory explanations, and our warehouses filled with materials for disinfecting the dreaded dejections, the tantalising word comes from a thousand sources that the supposed cholera germs are not by any means peculiar to the dejections from that disease, but may be readily cultivated as a *post partem* growth in any serous evacuation from the alimentary canal. From the tenor of these observations let no one infer that I undervalue the microscope as an aid in the study or investigation of medical topics. It has literally opened to us a wide and most important field of knowledge, and, when rightly used, is capable of adding much more. My object is simply to attract your attention to what has appeared to me the strongest barriers in the way of genuine progress, both in the science and art of medicine, namely: Incomplete observation of facts; deductions from inadequate premises, and the constant use of mere theoretical assumptions or suppositions as though they were demonstrated facts. It is the indulgence of these practices that actually keeps one-half of the professional observers busy in correcting the errors and disproving the assumptions of the other half, and fills our literature with endless contradictions. Almost every problem connected with medicine is complex, requiring for its proper solution a careful observation of many elements and their exact relations to each other.

#### THE BRITISH ASSOCIATION.

At the meeting held at Belfast, August 19th to the 26th, the Biological Section was divided into three departments—namely, Anatomy and Physiology, under Professor

Redfern; Zoology and Botany, under Dr. Hooker; and Anthropology, under Sir Wm. Wilde. Introductory addresses were delivered by each.

Dr. Pye Smith read a report of the committee appointed to investigate the nature of intestinal secretions. Experiments had been made to ascertain—1st. Whether other neutral salts had a similar effect to that of sulphate of magnesia on intestinal secretion; secondly, whether any other compound had the power of preventing such action; and thirdly, what nerves regulated those secretions during life. The results showed that several neutral salts possess a similar action to that of sulphate of magnesia. Sulphate of atropia, chloral hydrate, and other substances had no effect in diminishing the amount of secretion produced by sulphate of magnesia. With regard to the third point, it appeared that the splanchnic nerves are not the channel by which the currents from the cord pass to the secretory apparatus of the intestines. What the channel is the committee propose to ascertain by further investigation.

Mr. William Thompson, of Manchester, read a paper on "The Decomposition of Eggs."

Professor Cleland, of Galway College, brought forward a "Preliminary Notice of some Inquiries into the Morphology of the Brain and the Function of Hearing."

Professor M'Alister described "Some Anomalous Forms of the Human Periorbital Bones."

"Additions to the British Mollusca, and Notices of Rare Species from Deep Water off the Western Coast of Ireland" was a communication from Mr. Gwyn Jeffreys, in which he gave the result of his researches during a cruise in H.M.S. *Porcupine* in 1869.

In the Anthropological Department, Sir Duncan Gibb read a paper on "Longevity at Five Score Eleven Years," in which he mentioned the results of his examination of ten instances of persons who had overstepped the century. In the discussion which followed it appeared that there was a far larger number of genuine centenarians than was usually supposed.

Of other subjects worthy of mention were a "Report of Committee on the Chemical and Optical Properties of Essential Oils;" "Some Opium Derivatives," by Dr. C. R. Wright; "Cause of the Potato Disease, and the Means of its Prevention," by Mr. J. Torbitt; and "Report of the Committee on the Influence of Forests on Rainfall."

WEDNESDAY, SEPTEMBER 2, 1874.

### PROFESSOR TYNDALL'S ADDRESS.

WHAT can Professor Tyndall want? Standing in the post of honour, as the representative of Science, he is privileged to place before a select audience—and one that listens with profound attention—his views of nature, of man, of the origin of life—of whatever he pleases to dis-

cuss. These views are, to some extent, known, and are so completely in opposition to the opinions that prevail among men, that he evidently himself regards them as unpopular. Nevertheless, as we have said, he is listened to with profound attention. Fashionable society is as eager to honour him in Belfast as in Albemarle Street, and he is at liberty to preach materialism with all the power of his intellect and all the enthusiasm that the "dry light of science" can kindle within him. Surely here is liberty of which the age may be proud; and yet the learned professor adopts a querulous tone, and makes the aim of his address a vindication of the right of scientific men to investigate and to publish their conclusions on all subjects. Surely the day is past for disputation on such a theme. Professor Tyndall is in no danger of sharing the fate of Bruno, and the assumption that scientific men are likely to be burnt as heretics is, in the present day, simply ridiculous. But what else can we understand to be implied by the claim to discuss theories "whether right or wrong" because the "ground they cover is scientific ground." This may be so, but no one disputes the right which the speaker was at that moment exercising. Still, he considered it appropriate to say "the right claimed is one made good through tribulation and anguish, inflicted and endured in darker times than ours, but resulting in the immortal victories which science has won for the human race."

Here it is expressly admitted that the anguish has only been inflicted in "darker times than ours," and we take leave to state that, whatever discoveries may be made, science appears in no danger now, for though the people have no notion of deifying science, they have just as little wish to persecute her devotees; and the President of the British Association for the Advancement of Science chooses an odd moment to declare he must vindicate to the death the rights of thought when he occupies the post of honour, is the observed of all observers, when nobles and notabilities, wealth, fashion, and beauty listen, and his words are reported by telegraph to all the great daily papers, and thus sent wherever the English language is spoken. Strange perversity to expect persecution when columns of the *Times* are opened to special reports of his address.

But might not Professor Tyndall be conscious that he somewhat over-rated science and its claims when he asserted that "all religious theories, schemes, and systems which embrace notions of cosmogony, or which otherwise each into its domain, must, in so far as they do this, submit to the control of science and relinquish all thought of controlling it." This claim, though carefully worded, is large, and it might perhaps have sufficed to say they should relinquish the thought of controlling science without setting up the right of science to control them.

After all, it is not much that is offered in place of the religious theories thus ordered to stand aside; for Professor Tyndall admitted the insufficiency of science to satisfy man's need in this very address when he spoke of the religious sentiment as real; and said that "to yield it a reasonable satisfaction is the problem of the present hour." Whether we regard, with Professor Tyndall, matter as eternal, and the only indestructible part of the universe, looking on man as a

mere passing manifestation of a day—or whether we accept rather the more subtle notion of Berkely and others who set mind forth as the only essence—or whether we adopt a mixed view, such as millions entertain in spite of all metaphysical theories, and in opposition alike to all speculative systems, we cannot escape from ourselves, nor from our “environment,” and therefore the themes once more set in order before the Science Association command our lively interest. But even within the limits of the address we seem to feel that they are as unsettled as ever. “Can man by searching find out God?” Has science anything to offer us that may serve as more solid comfort than Job’s friends could offer him? This, we may be told, is not the end of science. If so, let science content itself within its own sphere, and not imitate those whom it so haughtily condemns for their attempts in time past to dictate to it.

If modern science is but a return to the philosophy of Lucretius and Epicurus, who formulated the “grand conception of atoms falling silently through immeasurable ranges of space into the arrangements out of which this visible system of things has been formed,” surely we are entitled to hesitate before we sacrifice everything at a shrine which is hallowed with none of that enthusiasm which is admitted to be a real part of our nature. Nay, if Empedocles saw the doctrine of the “survival of the fittest,” and evolution has been more or less a speculation present to individuals for ages, we should have reached a time when philosophers should not querulously demand the submission to authority they very properly refuse to practise themselves. Freedom of discussion by all means; but not for the materialists alone. They are more free than ever, and therefore Professor Tyndall’s complaint was quite uncalled for, and certainly his denunciations of the theories of others is curiously misplaced in an address full of speculation, and culminating in a confession of an attempt “to prolong the vision backward across the boundary of experimental evidence.” This, then, is the conclusion of those who set up experimental evidence as our only unerring guide. We are landed at the old boundary which man’s unaided intellect cannot pass. In spite of its interest, Professor Tyndall’s address is as inconclusive as others of its kind, and almost makes us wish for a return to the old practice of giving in the presidential address a summary of the progress of the year, eschewing those high themes on which men seem so unlikely to reach any satisfactory solution.

#### THE METRIC SYSTEM.

THE Metric System has such special interest to our readers that we may well quote in full the Report of the Committee to the Science Congress at Belfast. It was as follows:—

“The Committee appointed to report on the best means of providing for a uniformity of weights and measures with reference to the institute of science have already in their several reports indicated their opinion that such uniformity can best be promoted by the diffusion of the metric system in all civilised countries, and by the adoption of a system of coinage founded on gold, as a single standard with a uniform proportion of allowing of one in ten, and with a decimal division, and their opinion has been corroborated by the gradual extension

of the metric system notably in the whole German Empire, and by the concurrence of all nations in the same principle of coinage, though not in the identity of the unit. It is in the United Kingdom that the greatest difficulty is experienced in introducing the reform, and the Committee regretted that the Government had as yet taken no practical step in advance of the same. Meanwhile, however, the International Metric Conference had proceeded in their deliberations and in the manufacture of perfect metric standards, and the Committee hoped that as soon as a copy of the same should have been deposited in England, the Warden of the Standards will be authorised to verify by them the metric weights and measures in use in the United Kingdom, and that by this and other means the difficulties still in the way of the voluntary use of the same might be removed. The Committee having already done their best to diffuse information on the subject remitted to them did not think it necessary to recommend their re-appointment, and, in leaving the subject to be further matured by experience and time, reiterated their firm conviction that the uniformity of the weights and measures and coins would tend to the economy of time in the ordinary transactions of length, the extension of education and science, and the general advance of commerce and international intercourse.”

Notwithstanding the recommendation of the Committee, it was, after some discussion, again re-appointed, and certainly there are some reasons for satisfaction at this course. We have always sympathised with the desire to obtain an easy system of calculation that might bring us into closer relations with foreign countries, and always felt a regret that our differences should practically cut off so many from useful intercommunication. The statisticians are all in favour of a decimal system, and so many nations have now adopted it that it looks as if ultimately we should have to follow suit. The new German coinage is very nearly like our own, and its introduction is a sign of the times.

There is one point, however, in which medical men are perhaps behindhand; while always supporting the decimal system theoretically, they have practically deserted their principles. The clinical thermometer in this country is now widely in use, and we have by a sort of fatality for the most part stuck to the Fahrenheit scale. We submit that it is as important to science to have uniform thermometers as weights or measures. In this particular instance a little resolution at the commencement would have placed the records of clinical thermometers in all countries on a uniform scale. No greater oversight could have been committed by those who are anxious on the subject than to fail to enforce attention to the advantages of a single scale. Should not medical men now take up this question in earnest? It would be a fair subject for discussion at the International Medical Congress next year at Brussels. Meantime, let us take to heart the lessons of our own Science Congress.

An able speaker (Mr. Heywood) pointed out that the chymists, as a body, had taken up this subject most zealously, the Pharmaceutical Society having lately taken a division on the question whether they should adopt the system, when a most favourable opinion was found to prevail. It was suggested that influence should be applied in a quiet way to the proprietors of Cullen’s Arithmetic, the Messrs. Longman, in order to have the system introduced into that work, which was in such

general use in our schools. When the late Sir William Brown brought forward the subject in the House of Commons there was a large majority in favour of the proposal, and the Government of that day had gone so far as to coin a florin as part of the decimal system, but the present Government has gone back to the coinage of half-crowns, so we need not pretend to wait for the coinage. The metric system is now legal, though only permissive, though metric standards have not yet been verified in the same way as imperial measures. The system is already being taught in the higher class of schools, and the new Pharmacopœia is based on the metric system. The subject is therefore making progress. It is well known that the Associated Chambers of Commerce, ten or twelve years ago, unanimously resolved in favour of the system, and it was again this year stated by Dr. Farr that the Statistical Congress, held at the Hague, had passed resolutions to the effect that all statistical returns should be expressed in the form of the metric system, or, if according to our present weights and measures, a column should be provided for the same facts expressed in the metric system. The metric system is now almost universally used in France; Germany has recently adopted it; in Austria, Belgium, Italy, Spain, Greece, Switzerland, and the Southern States of America it has triumphed, and we must repeat that optionally the decimal system is already adopted in this country. From the tone of the discussion it was clear that the metric system had no opponent in the British Association. No one denied or disputed its utility. Is it not therefore strange that a system which has been of the greatest value to scientific men, and which has been so widely adopted, should not be adopted generally by the people of this country? Strange, however, as it may be, there are many excuses for the people who do not desire to change their modes of dealing and calculating. To the masses international communication does not seem important, and governments must consider the masses. To scientific men, however, it is easy to use the decimal system, and medical men have lost much by adhering to the Fahrenheit thermometer.

## Notes on Current Topics.

### Hospital Saturday Fund.

AN open-air meeting for promoting this fund was held on the 22nd ult. at Blackheath, under the presidency of Captain Mercier. A local committee for Greenwich and Deptford was appointed. It was announced that a grand *fête* in aid of the funds will be held at the Crystal Palace early in October.

### Action against an Insurance Company.

THE case of Dr. Jay *versus* the Gresham Life Assurance resulted in a verdict for the plaintiff on the 24th ult. The action was brought by Dr. Jay to recover £3,000, the amount of a policy effected on the life of his late wife; and payment was disputed by the company on the ground that material facts had been suppressed when the policy was effected. It was alleged by the defendants that

deceased was of intemperate habits, and a vast amount of contradictory medical evidence was produced. Dr. Jay denied that Mr. Dale, a surgeon at Scarborough, had spoken to him before the marriage, and had warned him that the lady was addicted to drinking and suffered from enlargement of the liver. Mr. Baron Amphlett, in summing up, alluded to the way in which the case had been got up, saying that Dr. Steele's letter was no doubt an attempt to get evidence for the office. His lordship condemned the practice of a great insurance company getting evidence in that way. As to the words in a letter from Dr. Jay to Dr. Steele, "I never knew until I was married and the life insured that Mrs. Jay's failing was of long standing," the jury would have to consider whether there was a reasonable construction to be put upon them. The jury, after five hours' consideration, gave a verdict in favour of Dr. Jay.

### Pure Water on board Ships.

SIR A. ARMSTRONG having urged upon the authorities the urgency of supplying pure water to Her Majesty's ships, a number of charcoal filters have been purchased. The filters are constructed on the charcoal block system.

### New Infirmary for Warrington.

It has been decided to erect the new Infirmary and Hospital for Warrington on the site originally fixed upon for it at Bank Park Gardens, Warrington, notwithstanding that considerable opposition had been made to that particular site by the Medical Committee.

### Doctors of the Olden Times.

SOME highly interesting and amusing anecdotes of the old physicians who have paced up and down Warwick Lane seem almost indispensable to a sketch, however brief, of the old College of Physicians, and of these Mr. Walter Thornbury, in Cassell's "Old and New London," gives some in his most chatty style. He begins with the famous Dr. Radcliffe, the first pre-eminent physician that arose after the removal of the college to the building erected by Wren in Warwick Lane. Radcliffe, a man eager for money, and of rough Abernethy manners, had the cream of all the London practice, when he lived in Bow Street, next door to Sir Godfrey Kneller, the great painter. He was brusque even with kings. When called in to see King William, at Kensington, finding his legs dropsically swollen, he frankly said, "I would not have your two legs, your Majesty, not for your three kingdoms;" and on another visit the Jacobite doctor boldly told the little Dutch hero—"Your juices are all vitiated, your whole mass of blood corrupted, and the nutriment for the most part turned to water; but," added the doctor, "if your Majesty will forbear making long visits to the Earl of Bradford" (where, to tell the truth, the king was wont to drink very hard), "I'll engage to make you live three or four years longer; but beyond that time no physic can protract your Majesty's existence."

Another sketch is of Dr. Wormald, or "Old Tommy," as the students called him. He was Abernethy over again in voice, style, appearance, humour. "Done for," was one of his pithy written reports on a "bad life" to an insurance

company, whose directors insisted that he should write his reports instead of giving them verbally. He once astounded an apothecary, who was about to put him and certain physicians off with a single guinea fee, at a consultation on a rich man's case, by saying, "A guinea is a lean fee, and the patient is a fat patient. I always have fat foes from fat patients. Pay me two guineas, sir, instantly. Pay Dr. Jeaffreson two guineas, instantly, sir. Sir, pay both the physicians and me two guineas each, instantly. Our patient is a fat patient." Some years since, rich people of a mean sort would drive down to St. Bartholomew's, and get gratuitous advice, as out-patients. Tommy was determined to stop this abuse, and he did it by a series of outrageous assaults on the self-love of the offenders. Noticing a lady, dressed in silk, who had driven up to the hospital in a brougham, Tommy raised his rich, thunderous, sarcastic voice, and, to the inexpressible glee of a roomful of young students, addressed the lady thus:—"Madam, this charity is for the poor, destitute, miserable invalids of London. So you are a miserable invalid in a silk dress—a destitute invalid, in a rich silk dress—a poor invalid, in a dress that a duchess might wear. Madam, I refuse to pay attention to miserable, destitute invalids who wear rich silk dresses. You had better order your carriage, madam." The lady did not come again.

#### Petrifaction versus Cremation.

DR. STEINBRIS, of Würtemberg, proposes to dispose of the dead by placing the body in a trough of cement, and then filling the space with liquid cement, which will harden and convert the whole into a solid mass of stone. The blocks thus obtained may be piled up, buried, or inscribed and set up to do duty as both tombs and tombstones. This method, if generally adopted, possesses some advantages for posterity, as future generations would probably use the obsolete blocks for building material.

#### Contamination of Aerated Waters.

WE have ourselves lately had an opportunity of verifying the remarks which have lately gone the round of the daily and weekly papers as to the foulness and unfitness of some aerated waters for drinking purposes. On having a bottle of aerated water opened on board one of our first-class steamers, the material was absolutely putrid, and smelt abominably. A comparative analysis of these waters from the various manufactories would be highly useful at a time when such unpleasant records are made public.

#### The Distribution of the Hospital Sunday Fund.

THE Committee of Distribution of the Metropolitan Hospital Sunday Fund have completed their task and published their awards of the amount realised, which amounted to above £29,500. Of this sum, £27,440 Gs. 1d. have been awarded to hospitals, dispensaries, and kindred institutions. The *Students' Journal* of Saturday last analyses the results thus:—

The following are the hospitals that have not been awarded grants, viz.: The British Skin Hospital, Great Marlborough Street (patronised by the Shah!); St. Peter's Hospital for Stone; the Throat Hospital,

Golden Square; the Hospital for Diseases of the Heart, Soho Square; Central London Ophthalmic, National Dental, and the Western Ophthalmic Hospital. St. John's Hospital for Diseases of the Skin made no application to participate. It will be observed that the list contains the names of some "specials" that we have always condemned as unnecessary, if not actually mischievous in their effects, and therefore undeserving of public support.

Last year the British Skin Hospital received from the Fund the sum of £47 18s. 4d.; St. Peter's Hospital, £38 6s. 8d.; the Throat Hospital, £191 13s. 4d.; and the Western Ophthalmic, £57 10s.; St. Mark's (for fistula) receives only £76 5s., as against £287 10s. last year; Royal Orthopædic, £76 5s., against £191 13s. 4d. last year; and the Cancer Hospital only £76 5s., against £239 11s. 8d. last year. We are pleased to see that the dispensaries have been more liberally dealt with than they were last year; also that the lion's share has been awarded where most wanted—viz., to the large unendowed general hospitals. Of these the London Hospital receives £3,821 10s.; St. George's £3,050; Middlesex, £2,287 10s.; University College, £1,220; St. Mary's, King's College, and Westminster, each £1,143 15s.; Charing Cross, £991 5s.; Royal Free and Seaman's, each £610; Poplar, £419 7s. 6d.; and the West London, £381 5s.

One point for which the Committee deserve great credit is the decisive blow they have inflicted on those clergymen who, instead of forwarding their collections to the Mansion House, distributed the sums to local charities, by deducting these sums from the amounts awarded to the several institutions. Had the Committee taken no notice of the sums transmitted direct to local charities, great injustice would have been done to other charities; moreover, this irregular distribution would have increased annually, and thus ensured the ultimate failure of this great and eminently worthy movement.

#### The Charge against a Parish Surgeon.

OUR readers will doubtless have observed in the daily papers a case of alleged assault brought by a patient, a young woman named Field, against Mr. Pope, of Brixton. The case has been before the court on three occasions, and was finally dismissed on Thursday last, the magistrate remarking that as the complainant's statements had been proved in several particulars by independent witnesses to be false, he was bound to give the defendant the benefit of the doubt, and dismiss the case. To us this is a very unsatisfactory ending. This woman charged Mr. Pope with a very serious offence, committed or attempted while in the discharge of his duties as a district surgeon. Either it is true or it is false; there cannot be any third issue. If true the defendant has been let off too easily; if false, his name has been added to the long list of victims of that unscrupulous class of women whose only object appears to be to extort money from innocent persons under threat of exposure, and whose position morally impels them to pay anything sooner than have their names dragged into print. This woman's evidence was contradicted over and over again, and the perjurer was allowed to go off scot free, side by side with the gentleman whose name, position, and future prospects she had done all that lay in her base power to ruin. We hope the case will not end here, but that we shall see the position of the two parties in the dock changed before many days are over.

#### The Propagation of Scarlatina.

THE following report will interest those concerned in the repression of such a dreaded scourge as scarlatina. We all hear of schools being broken up and families dis-

persed in an endeavour to force the lines of an outbreak of this disease, but the source hinted at is rather an unexpected one, and a very likely means indeed of propagating infections. At the last meeting of the Lincoln Board of Guardians a report was presented by Dr. Harrison, of the districts of Eagle Moor, Waddington, Potterhanworth, &c., who, in the course of his remarks, said that he looked upon village schools as the centres of contagion of scarlet fever in the rural districts, numbers of cases he had enquired into having been sent home ill from school. He thought those who had the authority to close school during the harvest time should certainly exercise their power, and close them during the prevalence of contagious fevers. People from infected houses, as they carry the disease of scarlet fever about in their clothes, should be prevented as much as possible from associating with others. He had lately heard of people going from houses in those districts infected with scarlet fever to church to attend a funeral; the service was read in church at two on the Sunday afternoon, and the ordinary service was at three o'clock.

### The Chorley Case of Malapraxia.

ANOTHER of those remarkable exhibitions of ignorance on the part of a country jury as to the responsibilities and duties of our profession towards the public has just been concluded at Liverpool. The facts of the case are, shortly, that the child of a labouring man met with a severe accident while at play, a compound fracture of both bones of the forearm, which subsequently ended in gangrene and amputation. All that followed was at the instigation of an illiterate "bone-setter" of Bolton, for the parents, when they called in Dr. James Rigby to see their child, made no complaint whatever, and therefore, as the learned counsel for the defendant justly observed, "but for the misfortune of their having fallen into the hands of a man so grossly ignorant as this Bolton bone-setter, who did not even know what was the envelope of the human body—whose knowledge was not even skin-deep," nothing would ever have been heard of this action for malapraxia. If there was any error in the treatment of the case, it resolved itself into a simple question as to whether the application of a few strips of plaister, which Mr. Rigby placed round the arm, had either directly or indirectly been the cause of gangrene. Admitting that it had any share in the subsequent unfortunate termination of the case, this amounted, at most, to a mere error of judgment, which the judge told the jury the defendant must not be held responsible for, but which, nevertheless, must have induced them to give a verdict for the plaintiff. What proved far worse than the application of the plaister was that of dragging the child from Chorley to Bolton to see Douglas, the bone-setter. This person, it appears, culpably removed the bandage and splint, and allowed the arm to hang down during a fatiguing double journey to and fro, while it was clearly shown by several eminent surgeons that Mr. Rigby pursued a course of treatment which they fully approved and sanctioned. We deeply sympathise with the victim of this malicious prosecution, and are therefore glad to see that an application has been made for a new trial, which we hope will take place in London.

### The Depths of the Ocean.

ONE of the most interesting fields of modern scientific research is that into the physical condition of the deep sea. As our readers are aware, a distinguished member of our own profession has taken the most prominent part in these important researches, and we looked with interest to the statements that were to be made by Dr. Carpenter at Belfast. He gave a most interesting account of the results of the cruises of the Challenger, and we doubt not that the near future has much to reveal to us in this direction. When we consider how small a portion of this field has been at present explored, and yet how rich has been the reward, we may well look forward with expectation.

Dr. Carpenter, in speaking of what has been already accomplished, estimated that over an area of 15,000,000 square miles the thermal stratification of the Atlantic had now been determined—that is to say, the distribution of temperature from above downwards in layers and strata comparable to those recognised by the geologist in the earth's crust. The Challenger Expedition, curiously enough, arose from the Fenian movement in Ireland. In 1868 Dr. Carpenter was on a visit to Professor Wyville Thomson. The attack upon Clerkenwell Prison had been made; a feeling of considerable alarm existed in the public mind, and numerous cruisers lay along our coasts. In these circumstances Professor Thomson suggested that they might get the use of one of these boats in order to make some deep-sea dredgings. On his return to London Dr. Carpenter made such representations as secured for them the use of the Lightning as a surveying vessel. Their first inquiries were carried on between the Faroe Islands and the North of Scotland. In that region of the sea, at between 500 and 600 fathoms, they found a temperature below freezing point, while at another part of the sea, and at the same depth, the temperature was 45°. Accompanying this there was a difference in the bottom and in animal life so complete, that at a distance of only a few miles they might bring up a mass of material similar to chalk, and which they now regarded as chalk in process of formation, and also animals resembling those of the old chalk type. On the other hand, a few miles off, the bottom being of barren sand, animals resembling sand animals were found, only known before as belonging to Iceland and Spitzbergen. These were found within 100 miles of the north coast of Scotland. In afterwards describing soundings which were made at one point in the Atlantic, Dr. Carpenter stated that two strata were found to exist, a deep glacial stratum coming down from the Polar area overlying the bottom, and over this another stream coming up and carrying a warm temperature with it. This he found subsequently was a general phenomenon in the Atlantic. In the Mediterranean, again, he found that the surface water in the heat of summer was heated up to from 75° to 80°; but this superheating ceased to manifest itself almost entirely at fifty fathoms. At 100 fathoms it disappeared altogether, and a uniform temperature was reached which extended to the bottom of the sea. In winter the temperature of the Mediterranean was from 50° to 54° over its whole surface from the top to the bottom. In summer the surface layer became heated to a certain extent by the rays of the sun, not so much by the direct

penetration of the sun's rays as by the concentration of the surface films by evaporation, and their sinking and carrying down their high temperature. In this way Dr. Carpenter formed the general idea of a great ocean circulation altogether independent of winds, altogether independent of the great horizontal movement of water of which the Gulf Stream was the most conspicuous example, and producing a most important effect in equalising the temperature of different parts of the ocean. He found that there was a continual flow from the bottom towards the equator along the deeper stratum; when the two polar flows met under the equator there was an upward movement, bringing polar water gradually under the influence of the equatorial sun; and then, as the convex of that, a movement of equatorial water, carrying the warmer equatorial water towards the pole, where in its turn it becomes cooled down by the polar atmosphere, and sinking, by its greater specific gravity, flowed back towards the equator as an under-stratum.

MR. E. BELLAMY, of Charing Cross Hospital, has been appointed to deliver the course of lectures on anatomy in the Government Art and Science Schools at South Kensington.

MR. CÆSAR HENRY HAWKINS, F.R.C.S., F.R.S., has been appointed President, and Mr. Jonathan Hutchinson, F.R.C.S., Hon. Secretary to the New Sydenham Society for the ensuing year.

At a special entertainment given in the Royal Foresters' Hall, Mile End, a few days since, the handsome sum of £94 10s. was cleared and handed over to the Treasurer of the London Hospital.

A MONTHLY NURSE was last week fined 40s. and costs, at the Clerkenwell Police Court, for having conveyed a servant suffering from scarlet fever to the Fever Hospital in two tramway cars successively.

We have much pleasure in learning that a Rowing Club has lately been formed at the London Hospital, which has received the most active support of both staff and students, Dr. Andrew Clark being President.

ONE of the few survivors of the Battle of Waterloo has just passed away in the person of Mr. Hawkins, M.R.C.S., who was assistant-surgeon on the cavalry staff at that memorable battle. Mr. Hawkins had passed four score years.

THE inhabitants of Maryport and vicinity have presented a handsome testimonial to Dr. John Nicholson Fleming, who had for many years been in practice amongst them, "in recognition of his private and public worth, on the occasion of his leaving Maryport to commence practice in Newcastle-on-Tyne."

At Wrington, North Gloucestershire, the inhabitants have been celebrating the marriage of the granddaughter of Dr. Young, formerly Surgeon to the 28th Regiment. Dr. Young served in the Peninsula from March, 1811, to

February, 1813, including the last siege of Badajoz and battle of Salamanca. He served also in the campaigns of 1813-14-15 in Germany, Holland, and the Netherlands, including the attack on Bergen-op-Zoom and battle of Waterloo. He has received the war medal with two clasps for Badajoz and Salamanca.

PROFESSOR GRANT, F.R.S., the distinguished zoologist, died on Friday, the 21st ult., in London. He was born in Edinburgh, in 1793, and received his early education at the High School. In 1808 he commenced his medical studies at the University, and finally became a Member of the College of Surgeons and M.D. of the University in 1814. After being in practice and delivering lectures on comparative anatomy for some years, Dr. Grant accepted the Chair of Comparative Anatomy and Zoology at University College, London. In 1837 he was appointed Fullerian Professor of Anatomy and Physiology at the Royal Institution of Great Britain.

## Association Intelligence.

### SHROPSHIRE SCIENTIFIC BRANCH.

THE annual meeting of the above branch will be held in the Natural History and Antiquarian Museum, at Shrewsbury, on Wednesday, September 9th, at 1.30 p.m., Wm. Eddowes, Esq., jun., President.

Papers on Hydrophobia and Chorea will be read, and others are promised.

The dinner will take place at the George Hotel at 4.30 p.m. SAMUEL WOOD, Honorary Secretary.

Shrewsbury, August 14th, 1874.

### MIDLAND BRANCH.

THE President of the above branch, T. Sympson, F.R.C.S., intends to hold a quarterly meeting at Boston during the month of September.

Members desirous of reading papers are requested to communicate at once with

C. HARRISON, Honorary Secretary.

Lincoln, August, 1874.

### NORTHERN COUNTIES (SCOTLAND) BRANCH.

THE annual meeting of this branch will be held in the Royal Hotel, Inverness, on Saturday, September 12th, at 11 a.m., J. J. Ross, Esq., M.D., of Inverness, President.

Particulars by circular.

The Council will meet in the same place at 10 a.m.

J. W. NORRIS MACKAY, Honorary Secretary.

Elgin, August 25th, 1874.

### NORTH OF ENGLAND BRANCH.

THE autumnal meeting of this branch will be held at Saltburn-by-the-Sea, on Thursday, September 17th, at 1.30 p.m., Andrew Legat, M.D., President.

The following papers have been promised.

1. Dr. H. J. Yeld: The Health and Mortality of Towns and Villages, as affected by Sanitary Legislation.

2. Dr. J. W. Macdonald: Catarrhal Pneumonia.

3. Dr. J. W. Eastwood: Case of Insanity, complicated with Partial Paralysis.

4. Mr. J. T. Parkinson: Case of Chronic Bright's Disease of the Kidneys (small contracted variety).

5. Mr. J. T. Parkinson: Case of Paracentesis Thoracis.

6. Dr. G. H. Philipson: Case of Hydatid Disease of the Liver, treated by puncture.

Gentlemen who desire to make communications at the meeting are requested kindly to communicate with the Secretary without delay.

Dinner at the Alexandra Hotel, Saltburn, at 4 p.m. Tickets, exclusive of wine, six shillings.

G. H. PHILIPSON, M.D., Honorary Secretary.

Newcastle-upon-Tyne, August 26th, 1874.

## Correspondence.

### ON THE THEORY OF COUNTER-IRRITATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Although I am somewhat surprised to learn that Dr. James Ross was not unaware of Fletcher's priority in the stimulant theory of counter-irritation, yet I am quite convinced, from his candid explanation, that he makes no claim of priority for himself, since finding that he was preceded by others, though he has the merit of having thought out the theory for himself. Fletcher appeals to the views of Lubbock, Allen, W. Philip, Black, Hastings, Gendrin and others in favour of the then new doctrine, that inflammation consisted essentially in a weakened action of the capillary tissue, and the theory in question is put forward as a natural corollary of that doctrine. He quotes any opinions of previous writers who have theoretically favoured the idea, and in particular, while explaining that with respect to epispastics, the benefit is, *ceteris paribus*, in proportion to the irritation and consequent stimulus, and not to the amount of discharge, he cites the saying of Stoll, "non suppuratio sed stimulus prodest." Nevertheless, he was the first, I believe, who expounded the doctrine in a complete and systematic form, and as harmonising with this whole system of pathology. It was taught publicly by him for ten years preceding 1836, and published in that year in his "Physiology", and more completely in his "Pathology" in 1842, and it has been believed in and acted on by his numerous pupils since that time. Dr. Ross claims originality in a small part of the application of the theory in that he says: "I have supplied a new machinery by which the stimulant action may be supposed to travel from the source of irritation to the diseased part. Fletcher believes that it is mainly owing to an action of the vessels, while I believe, on the contrary, that it is chiefly due to the proper parenchyma of the part." I think an attentive study of Fletcher's own works will show Dr. Ross that this is hardly correct. Fletcher held that inflammation and all nutrition and secretion were seated in the "capillary or parenchymatous tissue," which was the last word of anatomy then; and that the new irritation if near was propagated by contiguity, but if distant, by the reflex action of the nerves of organic sympathy, which corresponds pretty nearly to the central vaso-motor system of our day, and which harmonises also with the view of local ganglionic nerve-centres of Beale and Remak. In other respects, his theory was far more complete than that of Dr. Ross, for he held that vitality did not reside indiscriminately in the capillary or parenchymatous tissue, but solely in "diffused ganglionic nervous matter," which was hypothetically supposed to be spread through and interwoven with all living parts, and to the presence of which the vitality of any part was due. Upon this alone not only the stimuli which cured inflammation, but all other stimuli ultimately acted. This remarkable anticipation of the modern protoplasm theory will be brought before the public shortly in a small work which I have in the press.

Those who hold the stimulant theory of counter-irritants and revulsives, even when the disciples of Fletcher are reinforced, Ross and others who are reviving it form a small minority, and the recent discussions of the subject do not show any decided advance on the times of 1836, when Fletcher wrote (in his "Physiology," p. 135) that "medical men [were] destitute of the faintest outline of the shadow of an intelligible idea . . . of the operation of a so-called revulsive remedy." For instance, Mr. Jordan, in his attempt to revive the fashion of blistering, &c., as the universal remedy for inflammations, says (*Practitioner*, I., p. 79), "they probably remove a sum total of textural force (as Mr. Simon suggests) from the inflamed to another locality." This is not only simply unintelligible to other people, but it shows that the authors cannot have formed in their own minds any intelligible conception of the nature of life or force. And that this can be said of a hypothesis suggested by Mr. Simon goes far to justify the application of Fletcher's remark to the present generation.

Dr. Ross would do well to study Fletcher for other reasons also, for in his theoretical papers he is treading, for his own fame, perilously too nearly upon the path opened up by Fletcher; and he had much better frankly acknowledge and afterwards build upon what foundations he may have found correctly laid down by him. It is a

thankless task to re-discover what is already known and other eyes than mine are upon Dr. Ross, who perhaps may not judge him so leniently. Since my letter of the 5th August, I have heard from an old pupil and disciple of Fletcher, with whom I am personally unacquainted, who says that "Dr. James Ross continues to give Fletcher-and-water in the *Practitioner*" without acknowledgment of the source; and that the medical journals will not insert his reclamation of Fletcher's rights. This I have also found in respect to the *Lancet* and the *Medical Times* as well as the *Practitioner*, and it is a matter that those of our profession who are men of science and gentlemen, ought to look into. And this brings me to the most painful part of this subject, viz., the conduct of Dr. Anstie, who has as yet given no explanation. I have again read his statement in Vol. I p. 361, and I take it to mean a direct claim of having been the first to put forward the stimulant theory in 1861. That an editor should take advantage of his position to suppress evidence of priority in respect to a discovery claimed by him is surely not to be tolerated.

JOHN DRYSDALE, M.D.

Liverpool, 28th August, 1874.

## Medical News.

University of London.—The following are lists of the candidates who have passed the recent Honours Examinations:—

(FIRST B.SC. AND PRELIMINARY M.B. CONJOINTLY.)

### CHEMISTRY.

#### First Class.

Munro, J. May Herbt., First B.Sc. and Prel. Sci. (Exhibition, Coll. of Science, Dublin.

#### Second Class.

Uthoff, John Caldwell, Prel. Sci., Guy's Hospital.  
Wilkinson, Arthur, Prel. Sci. Owen's College Medical School.  
Smith, Alfred John, First B.Sc., Owen's College.

#### Third Class.

Capper, Thomas, First B.Sc., private study.  
Tilly, Alfred, Prel. Sci., St. Mary's Hospital.  
Smith, George, First B.Sc. and Prel. Sci. Royal School Mines.  
Crow, John Kent, First B.Sc. and Prel. Sci., Owen's College.  
Gill, First B.Sc. and Prel. Sci., Roy. Institution, Liverpool.  
Berry, Frederic Haycraft, Prel. Sci., Guy's Hospital.  
Wiglesworth, Joseph, Prel. Sci., Liverpool School of Medicine.  
Maylard, Alfred Ernest, Prel. Sci., Guy's Hospital.  
Sedgefield, Arthr. Robt. Wyatt, Prel. Sci. King's College.  
Wainwright, Robt. Spencer, Prel. Sci., Guy's Hospital.

### ZOOLOGY.

#### Second Class.

Hill, Alexander, Prel. Sci., University College.

#### Third Class.

Castle, Hutton, Prel. Sci., St. Thomas's Hospital.  
Gill, First B.Sc. and Prel. Sci., Roy. Institution, Liverpool.  
Wilkinson, Arthur, Prel. Sci., Owen's College Medical School.  
Williams, Dawson, Prel. Sci., University College.  
Smith, First B.Sc. and Prel. Sci., Royal School of Mines.  
Wiglesworth, Prel. Sci., Liverpool School of Medicine.  
Boulting, William, Prel. Sci., University College.  
Saiss, Walter, First B.Sc., Royal School of Mines.  
Shaw, John, Prel. Sci., St. Thomas's Hospital.  
Davies, William Edward, Prel. Sci., University College.  
White, A. H. S., First B.Sc. and Prel. Sci., University College.

### EXPERIMENTAL PHYSICS.

#### Second Class.

Tilly Alfred, Prel. Sci., St. Mary's Hospital.

#### Third Class.

Gill, R., First B.Sc. and Prel. Sci., Roy. Institution, Liverpool.

## BOTANY.

## Third Class.

Munro, J. May Herbt., First B.Sc. and Prel. Sci., College of Science Dublin.  
 Whitney, Neville Scott, Prel. Sci., University College.  
 Castle, Hutton, Prel. Sci., St. Thomas's Hospital.  
 Robertson, David, Prel. Sci., private study.  
 Wilkinson, A. T. Prel. Sci., Owen's College Medical School.  
 Wigglesworth, J., Prel. Sci., Liverpool School of Medicine.  
 Davies, William Edward, Prel. Sci., University College.  
 Williams, David James, Prel. Sci., University College.

## NOTICES TO CORRESPONDENTS.

**✉** CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

G. F.—Communication received.

G. Fox.—The matter shall receive our early attention.

E. T.—Communication received, and will appear in our next impression.

Dr. BALLARD has given the wrong title to a lecture which he says recently appeared in this journal. If he will forward more correct data the number will be sent him if in print.

Dr. H. M. J.—The information was too brief to be intelligible; sorry we could not use it.

Mr. HAYWARD, London Hospital.—We have received a copy of the rules, which is highly creditable. We heartily wish your enterprise success.

Dr. HARVEY.—In an early number.

A DISPENSARY MEDICAL OFFICER.—We refrain from publishing your letter, because we are unwilling to stimulate a feeling of jealousy between workhouse and dispensary medical officers, and as the question is settled, we see no advantage in debating the merits of candidates which—however great they may be—have not been recognised by Parliament.

Dr. DUDGON's letter was received too late for the present number; it shall appear in our next.

HAMPDEN.—We can express no personal opinion upon the capacity of any one to set bones unless we have had personal knowledge of his competency. Our mind is, however, made up on three points:—

1. That, inasmuch as the reduction of difficult dislocations is one of the most adroit proceedings in surgery, it is supremely impossible that it can effectually be done by any one who has not acquired a close practical acquaintance with both the anatomy of the parts and the necessary surgical manipulations.

2. That it is excessively improbable that any one can possess this knowledge unless he has received a careful surgical and anatomical education.

3. That most bone-setters achieve a reputation by the reducing dislocations which never existed, and curing sprains which they have themselves made.

4. That when a quack of any sort achieves a certain notoriety experience tells us that there will always be herds of fools (and not the less fools in this matter because they wear lawn sleeves or have a handle to their names) to believe in him and testify to assumed facts of which they have no personal knowledge whatever.

For these reasons we hold the opinion that no unqualified bone-setter is to be trusted.—Ed. M. P. & C.

OUR INDIAN CORRESPONDENT.—The pamphlet is in the hands of a writer who understands the subject, for an early notice.

MEDICAL JOURNALISM.—*Medical Notes and Queries*, which has carried on a lingering existence for two or three years, during which time its title was changed to the *Night Bell*, has at last ceased publication; the *Medical Record*, published in Paris in the English language, after two or three months of life, has also been suspended; and the *Echo de la Presse Médicale*, which started about the same time, will in future be published once a month only.

## DR. WEST AND "THE BRITISH MEDICAL JOURNAL."

The following resolution, passed by the Committee of Council of the British Medical Association at a recent meeting, has been forwarded to us by the solicitors to the Association, with a request for its publication in our columns:—

"Resolved.—That the Committee of Council regret that Dr. West does not consider the explanation of the Editor in the *British Medical Journal* of July 11th as satisfactory. They believe that the Editor has

acted with great courtesy in the matter and with perfect good faith. The Committee consider that the language in which Dr. West's letter is couched is uncalled for."

FALLEN LEAVES.—The fall of the leaf is invariably associated with a lowering of the tone of public health, and an increase of mortality. Has the fall of the leaf anything to do with it? There can be no doubt that it has. When the leaves fall we usually have warm wet weather, and the ground that is strewn with leaves becomes a nursery of morbid influences. In places where the fallen leaves are much crushed and stirred by feet and wheels the evil is aggravated, and of course on heavy lands the evil is of a more decisive nature than on absorbing sand, or chalk, or limestone. Where deciduous trees abound on clay lands, all the much-frequented roadways should be kept as clean as possible during the time of the fall of the leaf. The delightful odour that the fallen leaves diffuse in woods suggests their harmlessness, but on the roads and walks, where the leaves are hourly crushed and the dropping rain helps to make a paste of them, they are, without doubt, pe stiferous nuisances, and parochial authorities and private proprietors should cheerfully combine to mitigate the severity of the mischief they are capable of effecting.—*The Gardener's Magazine*.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Will you kindly say in your next issue if the coroner has the power of certifying for 15s. fee to a medical witness at an inquest; I have always got a guinea. I attended an inquest the other day, and received an order for 15s. I was always under the impression that the coroner should certify for the usual fee of one guinea. Does the law compel payment of so much?

Yours faithfully,

J. H.

[It is entirely at the discretion of the coroner—unless he acts at the special wish of the jury—whether he shall call in a medical witness at all; but if he does so he certainly must pay the proper fee of £1 1s. and has, we believe, no power to offer less. Possibly the summons has not been formal; if so, the coroner might pay anything, or nothing.—Ed. M. P. & C.]

COMMUNICATIONS, Enclosures, &c., have been received from Dr. Quain, London. Dr. Falconer, Bath. Dr. Balthazar Foster, Birmingham. Dr. Waters, Liverpool. Mr. Pearce, Plymouth. Mr. Dean, Salthwaite. Mr. Hinde, London. Dr. Morgan, Dublin. Dr. Moore, St. Bartholomew's Hospital. Dr. Maunsell, Dublin. Dr. James, Aix-la-Chapelle. Surgeon-General Gordon, London. Dr. Campbell Black, Edinburgh.  Hull Dispensary. Resident Surgeon. Salary, £150, with house, &c. Address the Hon. Sec.

Northampton Infirmary. Dispenser. Salary, £100 per annum. Further particulars of the Secretary.

York Lunatic Asylum. Resident Medical Superintendent. Salary, £300 per annum, with residence, vegetables, coals, gas, &c. Applications to the Committee, under cover to the Secretary, Bootham, York.  
 Newcastle-on-Tyne Infirmary. Senior House Surgeon. Salary, £100 per annum, with board and residence. Particulars of Dr. Page at the Infirmary.

Southport Convalescent Hospital. Resident Medical Officer. Commencing salary at £80, with board and attendance. Applications to the Chairman of the Hospital.

Gloucester County Prison. Surgeon. Salary, £175 per annum. Full particulars on application to the Governor.

Sunderland Infirmary. Junior House Surgeon. Salary commencing at £60 per annum, with board and residence. Address the Secretary to the Medical Board.

#### APPOINTMENTS.

CADDY, H., M.R.C.S.E., L.S.A.L., Junior House Surgeon to the Royal Southern Hospital, Liverpool.

FERGUSON, J., M.A., Professor of Chemistry at the University of Glasgow.

FRASER, J., M.D., C.B., an Hon. Physician to Her Majesty.

HEOBOTHAM, E., M.D., M.R.C.S.E., Medical Officer and Public Vaccinator for No. 3-4 District of the Shepton Mallet Union.

HYATT, J. T., M.R.C.S.E., L.R.C.P., Medical Officer and Public Vaccinator for No. 3-1 District of the Shepton Mallet Union.

JEFFERSON, T. J., M.D., M.R.C.S.E., Medical Officer for the Market Weighton No. 1 District of the Pocklington Union, Yorkshire.

JULIE, H. E., M.R.C.S., L.S.A., House Surgeon to the Female Lock Hospital, Paddington.

OWEN, Mr. C. A., Assistant House Surgeon to the Royal London Ophthalmic Hospital.

REID, G., M.B., C.B., House Surgeon and Secretary to the Staffordshire General Infirmary, Stafford.

WALKER, C. E., M.R.C.S.E., Medical Officer and Public Vaccinator for No. 8 District of the Chesterton Union.

WARSTER, J. H., M.R.C.S.E., L.R.C.P.Ed., Medical Officer and Public Vaccinator for No. 1 District of the Nottingham Union.

WILLIAMS, W., M.D., C.M., M.R.C.P.L., Senior House Surgeon to the Royal Southern Hospital, Liverpool.

ARMY—MEDICAL DEPARTMENT.—The Christian name of Surgeon-General Frazer, M.D., C.B., who was appointed Honorary Physician to Her Majesty in the *Gazette* of Aug. 11th, 1874, is "John," and not "James," as therein stated.

To be Surgeons Major—Surgeon S. K. Ray, vice H. M. Fraser, M.D., retired upon half-pay; Surgeon T. W. Wright.

To be Surgeons—L. B. Ward, Gent., T. J. Gallwey, M.D., W. B. Miller, M.B., G. B. Hickson, Gent., B. R. Ingle, M.D., J. Prendergast, Gent., W. S. Pratt, M.B., C. C. H. Smyth, M.D., J. A. Smith, Gent., J. Martin, Gent., P. S. Young, M.B., J. J. Greene, M.D., N. McCreery, Gent., J. A. Gormley, M.D., J. E. V. Foss, M.D., C. P. Turner, Gent.

#### Marriages.

ALFORD-SMART.—On the 26th ult., at All Saints' Church, Preston, Gloucestershire, William Alford, Esq., son of Stephen S. Alford, F.R.C.S., Haverstock Hill, London, to Mary Ellen Smart, of Northcote, Chichester.

DORIN-ARKINSON.—On the 27th ult., at All Saints', Notting Hill, Arthur F. L. Dorin, M.R.C.S., of Clapham, to Eva Catherine, daughter of the late Captain George F. Atkinson, Bengal Engineers.

KENNY-COLLINS.—On the 19th ult., at Holme-on-Spalding Moor, by the Rev. G. A. Shanahan, Pastor of Holme Hall, York, assisted by the Rev. C. F. Kenny, of Limerick, brother to the bridegroom, and the Rev. F. Correll, M. A. Kenny, L.R.C.P.Ed., to Annie Mary, only daughter of George Collins, Esq., Holme, York.

PAER-FRICE.—On the 12th ult., at Standish, Lancashire, William S. Paer, M.B. Lond., to Margaret Elizabeth, eldest surviving daughter of John Llewellyn Price, M.R.C.S., Standish.

#### Deaths.

ASHLEY.—On the 28th August, Wm. H. Ashley, M.D., of Ladbroke Square, London, aged 56.

BINDLOSS.—On the 22nd August, Jas. Bindloss, M.R.C.S.E., of Oakfield, Cheshire-Hulme, Cheshire, aged 45.

CAUTLEY.—On the 16th August, Henry Cautley, F.R.C.S.E., of Hedon, near Hull, aged 76.

CLARKE.—On the 22nd August, at Wood Green, N., Edward Griffiths Clarke, M.R.C.S.E., L.R.C.P.Ed., aged 81.

CONOLLY.—On the 24th August, at High Street, Camden Town, N.W., Michael Alfred Conolly, M.R.C.S.E., aged 43.

HAWKINS.—On the 27th August, at Colet Place, E., Jas. Hawkins, M.R.C.S., formerly Assistant-Surgeon on the Staff, Headquarters Cavalry, Waterloo, aged 80.

HILL.—On the 26th August, Samuel Hill, F.R.C.S.E., of Wimbomb, Dorsetshire (formerly Medical Superintendent of the North and East Ridings Lunatic Asylum, Clifton), aged 63.

JAMES.—On the 18th August, Edward James, M.D., of Parkfield, Portland Road, Edgbaston, aged 67.

JAMES.—On the 22nd August, Alfred James, M.D., of Argyle House, Forest Hill, aged 46.

LEITCH.—On the 28th August, John Leitch, L.F.P. & S. Glas., of Monteth Row, Glasgow.

Established 1848.

### PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S., &c. (King's Coll.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

Y 950. In the Suburbs of London, an OLD-ESTABLISHED PRACTICE, yielding £1,000 a year. Patients good class. All appointments have been declined. Visits, 4s. and upwards; midwifery chiefly £2 2s. and upwards. One horse and carriage sufficient for the work. The house is well situated in a pleasant and healthy locality, contains eight rooms, and is held on beneficial lease at a rental of £80 a year. The whole Practice is easily worked, and the connection lies within a small area. The Incumbent is retiring from the profession.

Z. 13. GLOUCESTERSHIRE. PLEASANT COUNTRY PRACTICE, realising about £500 a year, FOR TRANSFER. Midwifery fees chiefly £2 2s. No opposition. Appointments bring in £60. The house is convenient, with stabling, coach-house, &c. A thoroughly efficient introduction can be given.

Z 12. In a pleasant and prosperous town in the Midland Counties, A WELL-ESTABLISHED PRACTICE, yielding between £800 and £700 a year. Patients good middle class. The house is the best in the town, contains sixteen rooms, with offices, stabling, and coach-house. Rent, £90. A smaller professional residence can be had if required, as the Incumbent desires to enter upon a partnership conditionally arranged elsewhere. Liberal terms would be conceded to a suitable purchaser.

Z 11. Near the sea-side. In a pleasant town, a WELL-ESTABLISHED PRACTICE FOR TRANSFER on easy terms. The present receipts average about £470 a year. Easily worked appointments produce about £300 a year. No assistant required. One pony sufficient for the work. Large and convenient house, with garden, stabling, and coach-house. Rent, £30. There are about sixty midwifery cases a year, the majority at £1 1s. Only one opponent. Premium, one year's purchase, part of which may be left on security to suit the convenience of purchaser. An effective introduction as long as desired.

Z 10. NUCLEUS in LONDON, N. Great scope for increase. Very desirable residence. Rent, £75. Present receipts average about £10 a month. Fixtures to be taken at valuation. No premium required.

Y 982. EXCELLENT FAMILY PRACTICE in a prosperous and pleasant town, containing 28,000 inhabitants. Midwifery fees, £1 1s. to £5 5s. Receipts average £1,700 a year. The work can be done with one horse. A most effective introduction can be given, and to a doubly-qualified gentleman accustomed to good society the Practice presents a safe and desirable investment.

Y 999. PARTNERSHIP, with SUCCESSION, in an old Cathedral Town. The present receipts average upwards of £700 a year. The locality is picturesque, and there is great scope for increase. Books open to full investigation to a suitable gentleman accustomed to good society. Easy terms of payment would be conceded.

## THE LONDON HOSPITAL and MEDICAL COLLEGE.

The next WINTER SESSION will commence on Thursday, October 1st, 1874, when the Introductory Lecture will be given at 3 p.m., by SAMUEL FENWICK, M.D., Assistant-Physician to the Hospital.

General Fee to Lectures and Hospital Practice, 90 guineas, payable in two instalments of 45 guineas each. Library Fee, £1 1s. Specialties can be made to Lectures or Practice.

The Hospital contains 600 beds. The In-patients during 1873 were 5,613, and the Out-patients 43,803; total, 49,421.

The Following Prizes and Appointments are offered, without any further payment, to Students paying the general fee of 90 guineas:—

Seven Scholarships to be offered for competition in the Winter Session:

1. A Scholarship of £30 to the Student of less than three months' standing who passes in October the best examination in the subjects required at the Preliminary Examination.
2. A Scholarship of £20 to the Student of less than three months' standing placed second in the above examination.
3. A Scholarship of £20 in Human Anatomy for first year Students; to be awarded in April, 1875.
4. A Hospital Scholarship, value £25, in Anatomy, Physiology, and Chemistry, for first year and second year Students; to be awarded in April, 1875.
5. A Hospital Scholarship, value £30, for Clinical Medicine; to be awarded in April, 1875.
6. A Hospital Scholarship, value £30, for Clinical Surgery; to be awarded in April, 1875.
7. A Hospital Scholarship, value £30, for Clinical Obstetrics; to be awarded in April, 1875; and a Prize of £5 to the Student who has attended most Midwifery cases for the Hospital during the preceding twelve months.

The Duckworth Nelson Prize, value £10, for Practical Medicine and Surgery (Biennial), 1875.

Money Prizes to the value of £60 given annually by the House Committee for seal in Dressing Out-patients and knowledge of Minor Surgery.

For particulars as to appointments, &c., see the Prospectus, which will be forwarded on application to the Bedell of the London Hospital Medical College, Turner Street, E.

Further information may also be obtained from Mr. JAMES E. ADAMS, Treasurer, 10 Finsbury Circus, E.C.; or Mr. WARREN TAY, Vice-Dean, at the Medical College.

## SAINT MARY'S COLLEGE, CONWAY, N. WALES.

Conducted by Oxford and Cambridge University Men,  
A qualified Surgeon being a  
Resident Master.

The Course of Instruction comprises the Greek, Latin, French, and German languages; Classical Composition, English Grammar and Composition, Geography, Ancient and Modern History, Writing, Arithmetic, Mapping, Book-keeping, Algebra, Mathematics, Mensuration and Land Surveying, Drawing, Natural Science, and Music. Lectures are periodically delivered by the Principal on Natural Philosophy, Chemistry, and Astronomy, accompanied by illustrations and experiments.

## TERMS:—

£40 per Annum under 13 years.  
£50 " " over 13 "

These Terms include the whole Course of Instruction; but brothers are received at a considerable reduction.

## HOURS:

8 to 11, and 1.30 to 3.30. Preparations from 4 to 5.30. Dinner at 6, after which the boys go out under the care of a master for a ramble on the mountain or for a stroll on the sea shore. Pupils who are able to swim go, under the immediate care of the Head Master, for bathing at 11.15.

As a recreation, pupils are instructed (their Parents consenting) in Drilling (by a Commissioned Officer in the Army, who is also a Master in the College), Swimming, Rowing, Boxing, Fencing, Dancing, Single Stick, Gymnastics, and all the other requisites of a Gentleman's education—Riding and Driving alone being extras. There is also a Reading-room in the house, supplied with the principal daily and weekly papers, for the use of the Pupils. Great attention is paid to the morals and the manners of the Pupils. Corporal punishment is not allowed under any shape or form.

Monthly Reports of conduct and progress are sent to the Parents, and a Monthly Holiday is given by the Head Master to those Pupils only who have given satisfaction during the month.

The Michaelmas Term will begin on the 1st September; Lent Term, 1st February; and Easter Term on May 1st.

No notice is required before the removal of a Pupil, and boys may enter at any time, charge only being made for the part of the Term during which they have been present. Fees for one Term to be payable in advance—the balance in case of removal will be returned.

Applications for admission to be made to J. R. KENNEDYBELL, Esq., 9A Sackville Street, London, W.

## WESTMINSTER HOSPITAL MEDICAL SCHOOL.

Opposite WESTMINSTER ABBEY.—The SESSION 1874-5 will commence on THURSDAY, OCTOBER 1st, with an Introductory Lecture by Dr. POTTER. The Address will be followed by the Distribution of the Prizes, and a Conversation in the Board-room. The new Physiological Laboratory will be completed by October 1st.

The Examination for the Entrance Scholarship will be held on the 2nd and 3rd of October.

5th August, 1874.

GEORGE COWELL, Dean.

## BRISTOL MEDICAL SCHOOL.

The WINTER SESSION will commence on THURSDAY, October 1. Prospectuses may be obtained on application to

GEORGE F. BURDER, M.D., Hon. Sec.  
Medical School, Old Park, Bristol,  
August, 1874.

## ST. THOMAS'S HOSPITAL, ALBERT EMBANKMENT, WESTMINSTER BRIDGE, S.E.

The MEDICAL SESSION for 1874 and 1875, will commence on THURSDAY, the 1st OCTOBER, 1874, on which occasion an ADDRESS will be delivered by Mr. MACCORMAC, at Two o'clock.

Gentlemen entering have the option of paying £40 for the first year, a similar sum for the second, £30 for the third, and £10 for each succeeding year; or, by paying £105 at once, of becoming perpetual Students.

Private Classes for Students preparing for Matriculation, and for the Preliminary Scientific Examination of the University of London, or for other Examinations, are conducted by members of the Staff, and embrace instruction in Chemistry, Natural Philosophy, Botany, and Comparative Anatomy. These Classes can be attended without entering at the Hospital.

## PRIZES AND APPOINTMENTS FOR THE SESSION.

THE WM. TITE SCHOLARSHIP, founded by the late Sir WM. TITE, C.B., M.P., F.R.S., the proceeds of £1,000 Consols, tenable for three years.

First Year's Students. WINTER PRIZES—£20, £15, and £10. SUMMER PRIZES—£15, £10, and £5.

Second Year's Students. WINTER PRIZES—£20, £15, and £10. SUMMER PRIZES—£15, £10 and £5. The Dresserships, and the CLINICAL and OBSTETRIC CLERKSHIPS.

Third Year's Students. WINTER PRIZES—£20, £15, and £10. Mr. GEORGE VAUGHAN'S CHERLTON MEDAL. THE TREASURER'S GOLD MEDAL. THE GRAINGER TESTIMONIAL PRIZE. THE TWO HOUSE PHYSICIANSHIPS. THE TWO HOUSE SURGEONIES. THE RESIDENT ACCOUCHERSHIPS. TWO MEDICAL REGISTRARSHIPS, at a Salary of £40 each, are awarded to Third and Fourth year's Students, according to merit.

The SOLLY MEDAL, with a Prize of at least 10 Guineas, will be awarded at the end of the Session, to a Student of the Third, Fourth, Fifth, or Sixth years, for the best Report of Surgical Cases.

## MEDICAL OFFICERS.

HONORARY CONSULTING PHYSICIANS.—Dr. Barker and Dr. J. Risdon Bennett.

HONORARY CONSULTING SURGEON.—Mr. Frederick Le Gros Clark.

PHYSICIANS.—Dr. Peacock, Dr. Bristowe, Dr. Clapton, Dr. Murchison.

OBSTETRIC PHYSICIAN.—Dr. Barnes.

SURGEONS.—Mr. Simon, Mr. Sydney Jones, Mr. Croft, Mr. MacCormac.

OPHTHALMIC SURGEON.—Mr. Liebreich.

ASSISTANT PHYSICIANS.—Dr. Stone, Dr. Ord, Dr. J. Harley, Dr. Payne.

ASSISTANT OBSTETRIC PHYSICIAN.—Dr. Gervie.

ASSISTANT SURGEONS.—Mr. F. Mason, Mr. Hy. Arnott, Mr. W. W. Wagstaffe.

DENTAL SURGEON.—Mr. J. W. Elliott.

ASSISTANT DENTAL SURGEON.—Mr. W. G. Ranger.

RESIDENT ASSISTANT PHYSICIAN.—Dr. Turner.

RESIDENT ASSISTANT SURGEON.—Mr. McKellar.

APOTHECARY.—Mr. R. W. Jones.

MEDICINE.—Dr. Peacock and Dr. Murchison. SURGERY.—Mr. Sydney Jones and Mr. MacCormac. GENERAL PATHOLOGY.—Dr. Bristowe. PHYSIOLOGY and PRACTICAL PHYSIOLOGY.—Dr. Ord and Dr. John Harley. DESCRIPTIVE ANATOMY.—Mr. Francis Mason, and Mr. W. W. Wagstaffe. ANATOMY in the DISSECTING ROOM.—Anatomical Lecturers.—Mr. Rainey and Dr. W. Reid. PRACTICAL and MANIPULATIVE SURGERY.—Mr. Croft. CHEMISTRY and PRACTICAL CHEMISTRY.—Dr. A. J. Bernays. MIDWIFERY.—Dr. Barnes. PHYSICS and NATURAL PHILOSOPHY.—Dr. Stone. MATERIA MEDICA.—Dr. Payne. R. G. WHITFIELD, Medical Sec.

Any further information required will be afforded by Mr. WHITFIELD.

## ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—The WINTER SESSION will commence on THURSDAY, 1st OCTOBER, with an Introductory Address by Dr. Dickinson, at 4 p.m., in the Hospital.

The system of Clinical Teaching has been arranged so as to afford every student personal instruction in the wards from the Physicians and Surgeons themselves.

The courses of Lectures on Physiology and Surgery have been remodelled in conformity with the new regulations of the College of Surgeons.

Special departments have been organised for practical instruction in Midwifery, Ophthalmic Practice, Skin Diseases, Vaccination, and Dentistry. Lectures on Public Health are given by the Lecturer on Medicine.

Pathology, Morbid Anatomy, Psychological Medicine, and Comparative Anatomy are taught in distinct courses.

Instruction is given in all the special modes of medical and surgical investigation.

The following paid offices are offered for competition annually—viz., Obstetric Assistant, Curator of the Museum, Demonstrator of Anatomy, Medical and Surgical Registrars.

The House-Physicians and House-Surgeons are selected by merit from among the Perpetual Pupils without payment, board and lodging in the Hospital being provided at the expense of the Governors.

The Wm. Brown Exhibitions of £100 per annum, tenable for two years, and £40 per annum, tenable for three years; the Brackenbury Prizes of £35 each annually, are awarded, along with various other prizes, by competition among the students.

The prospectus may be obtained by application to the Secretary at the Hospital, and any further information will be given by Dr. Barclay, Treasurer, or Dr. Wadham, Dean of the Medical School, either personally or by letter.

### ILLUSTRATIONS OF THE LITERATURE OF QUACKERY. (a)

By HENRY GIBBONS, M.D.,  
Editor of the *Pacific Medical and Surgical Journal*.

THAT "people like to be humbugged" is a saying more practical than elegant; and it is exemplified, more than in any other way, in the universal currency given to impostors and impostures that concern the public health. Physicians are often censured for not taking more pains to separate the false from the true, the spurious from the genuine, in medicine and medical practice, so that people may discriminate between them. If the discrimination were made, it is not certain that the popular current would be turned in the right channel. There is no doubt that many persons would be more attracted, as indeed they are already, by the meretricious trappings of charlatany than by the more sober claims of science and truth. Whether for good or for evil, I propose, on the present occasion, to give utterance to some thoughts and observations bearing on this subject.

A large proportion of the patent and secret medicines with which simple-minded people delight to experiment on their organs, have been stolen from the regular profession. A patient who believes that he has been cured by a certain prescription grows enthusiastic in favour of the remedy, and recommends it indiscriminately. It is surprising what multitudes of men and women will advise medicines and what multitudes will swallow them on this primitive logic.

With better judgment and better opportunities, apothecaries sometimes prostitute their office and beget nostrums. Behind the counter, handling prescriptions, they have frequent means of ascertaining the effects of certain agents or combinations on certain diseases. Appropriating to their

own illegitimate purposes the knowledge thus procured through the patients of the medical man who confides to them his prescriptions, they add to the already prolific spawn of secret cure-alls. Thus they become not only prescribers but quacks and nostrum-mongers.

The only female apothecary I ever knew flourished in my native town in the State of Delaware, when I was a lad. She was well educated for that day, and she educated herself still further by gathering from her customers all the information she could obtain as to the diseases which the prescriptions that they brought to her were designed for and the effects. This information she recorded in a book kept for the purpose. Her ingenuity and industry were rewarded by a valuable clinical record, more complete and more practical, most likely, than any which were kept by the doctors who wrote the prescriptions. In this way she learned the art of prescribing. It so happened that my father, who was a physician, was in the habit of prescribing for the flatulent colic of infants a mixture containing oil of anise, with magnesia or chalk. The female apothecary soon discovered the value of the preparation, and forthwith engaged in the manufacture and sale of it on her own account, announcing it as "*Dr. Gibbons's Colic Drops*." My father detested quackery in all its phases, and I well remember his consternation when he discovered that his prescription had been converted into a nostrum and his name identified with it in this manner.

I may remark in passing that "*Mrs. Winslow's Soothing Syrup*" owes much of its virtue to oil of anise, and that it is essentially a mixture of this oil with morphia—the latter in variable proportions, but in quantity sufficient to have proved fatal in a number of well-attested cases. In fact, "*Mrs. Winslow's Soothing Syrup*" is one of the most dangerous nostrums in the market; nevertheless, it is sold by apothecaries in general, and by some even placarded conspicuously in their windows!

The senior members of the profession will recollect a long string of "panaceas," "catholicons," pulmonic balsams, and so forth, commencing with "Swain's Panacea," about half a century ago. An ignorant book-binder in New York, who could not even write his name, contrived a disreputable disease, for which he was

(a) Read before the California State Medical Society at the Annual Meeting.

treated by Dr. Quackenboss, then an old practitioner in that city. He was cured by the aid of a preparation of sarsaparilla, similar to the French *syrup de cuisinier*, the formula for which the doctor kindly gave to his patient, that he might save expense by manufacturing it for himself. Swaim removed to Philadelphia, and conceived the idea of turning his personal experience to profit. He made a quantity of syrup and took it to the Pennsylvania Hospital, and asked permission to give it to some of the patients. The patients appeared to be benefited, and Swaim then requested Professors Chapman and Gibson, visiting physician and surgeon of the Hospital, to give him their estimate of it in writing. This they did, thoughtlessly, after being apprised of the ingredients. Shortly afterwards "*Swaim's Panacea*" came out in the newspapers in flaring capitals, with the certificates of the two distinguished professors, which also headed a large pamphlet filled with certificates of wonderful cures performed by it. At once the nostrum was received into popular favour, and the sales of it soon became enormous. It was even exported in large quantities to the West Indies, South America, and Europe. Swaim, who had learned to write his name in order to affix it to his labels, made a splendid fortune, and built himself a palatial residence in Chestnut Street. Both he and his distinguished endorsers have gone to their long rest—he exultant with triumph, the professors annoyed to the last by chagrin.

Some thirty years ago there lived in the southern part of New Jersey a mechanic, or labouring man, who suffered a long time from chronic diarrhoea. He was cured at last by a prescription obtained from a physician residing, I think, at Port Elizabeth. He removed to Philadelphia and transformed himself into a doctor more promptly and more economically even than doctors are wont to be made by the bastard manufactory of the man called Dr. Buchanan. And so "Dr. Jayne" and his "Carminative Balsam" had their birth. By the foolishness of advertising the Carminative Balsam became a success. The name of Jayne acquired value as capital in trade, and was used to give currency to vermifuges, expectorants, and other preparations. And thus did the obscure and ignorant farm-hand become a doctor and a millionaire, not so much by his brains as by the accident of a bowel complaint.

If the charlatan be an ignominious, he must employ some one to run the literary department—to write up advertisements and certificates of cure. The imagination of an adroit liar is capable of supplying the certificates. These require a professional varnish, however, and for this purpose it is customary to hire some thread-bare doctor—some child of genius and misfortune who has fallen by the wayside in the battle of life, and who sells his soul to save his body from starvation.

The "natural bone-setters" are a curious variety of the human race. They possess by nature the gift of bone-setting, handed down from the seventh son of the seventh son, or some equally valid inheritance. It was my good fortune, just after taking my degree in medicine, to fall in with "Doctor Sweet," the great natural bone-setter of that period, and to enjoy a half day's clinic at his elbow. He had come all the way from Connecticut, or New York, at the solicitation of some individuals of easy faith, to manipulate a lot of cripples in my native town; and I was glad of the opportunity to accompany him and witness his performances.

One of the patients on whom I saw him operate was an Irish gentleman, with sub-acute rheumatism of one arm, every joint from the shoulder to the extremities of the fingers being stiffened and painfully sensitive. He began with the shoulder, twisting and turning the inflamed joint forcibly in all directions, remarking—"I will soon fix it for you."

"Doctor," I enquired, "do you consider that joint dislocated?"

"No, it is shot," was the answer.

"You mean it is out of joint?"

"No, I mean no such thing. It is shot."

"Well, you mean to say the bones are not exactly in place."

"I mean just what I say, the joint is shot."

And that was the only idea of his pathology that I could gather. From the shoulder he proceeded downwards, using the same forcible movements with each joint. Reaching the fingers, he planted his thumb in the palmar surface of every articulation and bent the joint with violence, the poor patient roaring with agony at each successive operation, and begging piteously that the delicate process be suspended long enough for him to swallow a glass of brandy. It is needless to say that injury, not benefit, followed such treatment.

Sweet was extremely ignorant, and purposely so. He knew that success in a man of no education would dazzle the vulgar; and he knew also that the term *vulgar*, in that application of it, includes people generally. He intended that his "gift" should sparkle like a diamond on a dung-hill. His pathology was embraced in the one word, "shot;" and his therapeutics in the one word "fix." He often fixed a greater number of bones than are counted in osteology. A medical student who was present on the occasion referred to, now Dr. R. R. Porter, of Delaware, asked him if he had ever examined a skeleton. He did not know the meaning of the word, but exclaimed, after a repetition of the inquiry, "Oh! you mean an *anotomy*. I seen one once, but did not examine it. I had no occasion to do so. I don't want to know any thing about the bones. It might interfere with my gift."

Old Californians will remember "Dr. Young," the pioneer quack of the Pacific Coast. He was an upholsterer and nothing more, until his sudden transformation into a doctor, which required but a single night. He flashed into fame and into business through the institution which graduates nearly all the quacks in the world—the newspaper press.

There was a vein of honesty in Young's character. Realising his own inability to treat disease, he prescribed by proxy. Of this I was first apprised by the following incident. Being called in consultation in the case of a sick child, late in the evening, it became necessary to appoint an hour for another meeting with the attending physician on the day following. That gentleman was a well educated medical man, but unfortunately he had been ensnared and shorn of his locks by the Circe of our profession. He could meet me only before eight in the morning, and after six in the evening. I was much surprised by this announcement, until he explained the reason. "I am ashamed to own it," said he, "but I am in the service of Dr. Young. I have a family, and I could not see them starve. My professional pride is humbled by the position, but the case is one of necessity. Young never prescribes for his patients. He sits at the desk in the reception-room and arranges and receives the fees, and then refers them to me in the private office. I pass for the doctor, and Young for my clerk. He pays me \$250 a month, and my time is his exclusively, from 8 A.M. till 6 P.M."

Both these individuals have long since gone to their graves. But "Dr. Young's Institute" still lives, and his name is still employed to attract persons who are fond of certain flavours.

Twenty years ago there was a shop boy in a dispensary in this city who performed the duties of his office for the moderate compensation of \$40 a month. He was of European birth, well educated, and of pleasant manners, attentive to business and economical. He withdrew amicably from the service of his employer, and investing his savings in the press, he came forth one morning as a newspaper graduate, a full-fledged physician and surgeon, of infinite celebrity and experience in Europe. He was the most adroit and gentlemanly of our California charlatans, and perhaps the best qualified and the most successful. Some time after this *début* he announced himself as a graduate of the regular Philadelphia school. Regarding this as impossible, I wrote to the dean of the school for information, and learned that it was really so, and that he had obtained an *ad eundem* degree by exhibiting anti-

monials of the highest order from medical schools in Europe. The mystery was subsequently explained by the discovery that he had a brother in Philadelphia whose testimonials he had borrowed, and whose character he had assumed. His career was brilliant and lucrative. In the list of treasure shipments published at the departure of the steamers, his name always appeared as a large shipper. It was ascertained however that he was in the practice of paying other shippers to enter their remittances in his name.

Thus "by hook and by crook" did he accumulate a fortune sufficient to warrant him in retiring from business. Shaking from his feet the dust of quackery, he mounted to a respectable position in society, and now enjoys his *otium cum dignitate*, unmoved by needless contemplation of the hole of the pit from whence he was digged.

In former years a man named Jones held forth in Washington Street, as the author and vendor of a "Lucina Cordial," which would strengthen the nerves, impart sexual vigour, and cure all irregularities of females. This man sent for me to prescribe for his wife. Her case, as represented both by her and by himself, was so exactly that for which the "Cordial" was advertised as an infallible cure, that I could not avoid asking him if he had tried it on her. He answered with a significant movement of one eye, "I don't give that in my own family."

In California, as in all other parts of the world, there are "Worm Doctors." Some man of stomach becomes a victim of parasites, and is made acquainted through a medical prescription with the virtues of male fern—the insecticide mostly employed by these worm-killers. Forthwith he gathers up all the tape-worms and other entozoic prodigies which cats, dogs, and human beings can supply, displays them in his window, and talks and writes tape-worm, knowing that a large percentage of men and women who see and read will be converted, and will come for his medicines. On this hobby has many a perfect ignoramus crawled into celebrity and affluence.

There is an old story of two fellows who embarked in a speculation in itch-ointment. One of them had the disease, and travelled through the country shaking hands most affectionately with every body. The other, who had the ointment, followed in a week or two, selling the cure. A game something like this belongs to the art of quackery. The first step is to make patients, and this can be done by getting people to read about disease. Pamphlets, almanacs, newspapers, distribute the infection. It requires but little knowledge of human nature to discover that reading of diseases causes persons to fancy themselves sick, and sometimes even makes them sick.

The weakest part of a man's body in this respect is the sexual apparatus. It is the easiest thing in the world to convince a man who has ever been diseased in these organs that the disease is still in his system, or to convince him that he is suffering, or will suffer, from indiscretions, however trifling, of his former life. Here are the two cords on which charlatans play with terrific success—private disease and seminal weakness. In this city, as in every large city in the world, there are at any given time hundreds, if not thousands of men, who have been startled from their daily labours in the mines and fields and workshops by reading the well-devised, sensational advertisements which pollute the columns of almost every newspaper. Gathering up their hard earnings, they hie them away to the city and rush into the trap. Their fears are realised, their apprehensions are promoted, and a cure is guaranteed for a fee in advance. Once in the toils, their course is onward and downward, for ever. Without employment, they spend their time in travelling to and from the pool of infection; brooding over their thousand sufferings, fancied and real; perusing the poison literature of quackery; giving and receiving increased trouble by comparing notes with other sufferers like themselves; until, their last dollar and their last hope gone, they lay down to die in a public hospital, or spend their last days in gibbering idiocy.

It is a great mistake to suppose that quackery is a plant which grows only on the miry soil of ignorance. On

the contrary, many of the most mendacious and successful quacks are well educated men and graduates of medical institutions; and many of the best patrons of such impostors belong to the polite circle of society. We have seen in this city a semi-barbarian Asiatic, but little above a brute in intellect and knowledge, patronised by the families of intelligent merchants and bankers. And the most adroit and unprincipled charlatan, perhaps, who ever flourished on the Pacific coast, was a graduate of London.

"Anatomical Museums" as they are called, are advertisements which conceal their real purpose. A large collection in wax exhibits the effects of disease on the organs of generation in both sexes. There is enough of anatomy and pathology in the collection to impart a scientific flavour to the otherwise corrupting and disgusting exhibition. A lecture is embraced in the programme, and this lecture is cunningly framed for the purpose of seducing credulous and imaginative hearers into the belief that they are diseased, and thus drawing them into the toils.

Several years ago I published in the *Pacific Medical and Surgical Journal* the description of an interview which a gentleman of this city had with the proprietor of the museum, and which I procured from his own lips. It was in substance as follows: "The patient is scarcely sick—does not know whether he is sick or well—has heard a lecture at the 'Anatomical Museum,' which is part of the plan, and which has started some apprehension in his mind. A fee of \$5 or \$10 secures a hearing. The urine must be examined while the patient waits. If he be a man of consequence in the community, the 'doctor' puts on large airs and keeps him waiting an hour or two, in the style of the Pontiff and Prince Henry. Finally, the strutting finished, and the impatient patient sufficiently impressed with the preliminary demonstrations, the mountebank sits at his side and proceeds solemnly, 'Now, Mr. Shivers, you must control your feelings and remain composed. I don't wish to alarm you, sir, but you are in a bad way. Your urine is full of animalcules. The microscope shows them plainly. Be tranquil, sir; your case is not desperate: but your blood is full of spermatozoa. Let me show you the danger, sir. (Here the artist draws on paper two parallel lines to represent a bloodvessel, and pencils a number of eels wriggling along endwise). Now, sir, as long as the animalcules swim endwise there is no difficulty. They circulate all about the body without injury. But let one of them get crosswise, so. Don't you see the effect?—to obstruct the bloodvessel instantly? And then you drop dead, sir.'" "Well, doctor, can you cure me? and on what terms?" asks Mr. Shivers. "Certainly, sir; I have two methods. One is the more speedy, but very costly. It requires a medicine which is very expensive. It will cost you \$500. The other is the more common method, and will cost \$300." If the patient is sufficiently psychologised he pays down the money, if he has it. But if he begins to argue on finance, he is told to take time to consider, and to call again. The chances are largely in favour of his returning.

A few years ago a certain healer of disease came down upon us like a divine presence, his feet "scarcely deigning to tread the earth"—in fact, refusing to do so for less than \$50 a visit. He advertised in the newspapers to such an extent that it was rumoured that some of them had entered into partnership with him.

Our people have not forgotten the "King of Pain," who dashed through the State in a splendid vehicle with six white horses, scattered like autumn leaves his advertisements of aconite liniment, the virtue of which he had grown acquainted with by some accident. His knowledge of the materia medica was bounded by this one article, but he was an expert card-player, and invested in gambling the proceeds of his speculation in human credulity. He travelled very fast, and came to a miserable end, through a greater "pain killer" than aconite.

The types of the printer are made to do more pure, un- of the beer-shop, and before long it will be as disreputable

adulterated falsehood, with a smaller portion of truth, in the service of quackery, than in any other department of their application. No person who embarks in the career of charlatanism, or who undertakes to push a nostrum, can have the least hope of success without first throwing away his conscience, and either at once by deliberate design, or slowly by insensible gradations, selling himself to the Father of Lies.

Perhaps I should not have left the peaceful fields of medical inquiry to make this foray upon the bandits of society, were it not for personal grievance. Some twelve or fifteen years ago an individual, somewhere in the mining region, dropped his pick and shovel, and came to this city to practise medicine. His medical education was accomplished whilst the earth was making a single revolution on its axis. To-day he was John Fitzgibbon—to-morrow, "Dr. J. F. Gibbon;" and the transformation was rendered available by ornamenting the walls, and casks, and boxes throughout the city with a handbill displaying a photograph of Esculapius, and announcing "Doctor Gibbon's Dispensary," for the cure of a certain class of disease. At the same time the newspapers of the Pacific coast were stocked with the same advertisement. As I had been in practice here ever since 1850, and had two brothers also practising in medicine in other parts of the State, the name was well-known; and the imitation, in fact, the assumption of it, was too bare-faced an imposture to admit of doubt as to the motive.

From that time to the present I have been the recipient, personally and by letter, of applications for "patent French safes," and for the means of producing abortion, and for the treatment of "weaknesses" and loathsome diseases—applications made in the belief that I was the author of the filthy advertisements in question. Such things show how many persons there are in a community supposed to be intelligent, who are ignorant that the advertising of one's qualifications and cures is held to be dishonourable and disgraceful among all educated and respectable physicians; and that it is invariably a mark of incompetency or of fraudulent design, frequently of both. They also serve to illustrate the extreme loathsomeness of the business carried on by the advertisers in general, and its hostility to the physical and moral interests of its dupes and victims.

The relation of this system of advertising to the practice of criminal abortion is no trifling matter. Advertisers generally manage to convey covertly to parties concerned the intimation of their readiness to perpetrate this crime. They talk of removing female obstructions, and so forth, or they resort to the trick of advising pregnant women not to take their medicines; and though the purport of such publication is well-known, yet there are few conductors of newspapers who refuse to print and circulate them, and thus make themselves accomplices. Thus advertisers and editors are in the daily practice of doing under cover, but knowingly, what would be felony if done openly.

I will not say that advertisers are all abortionists, but I do say that when men calling themselves "doctors," go into the advertising business, they identify themselves with impostors and abortionists, and have no claim on the respect or confidence of society. They throw their reputation on the market and sell it for gold. Their conduct demonstrates that, if they are not abortionists, it is only because the pay is less in that direction.

Certificates of cure with which charlatans bait their hooks are the weakest and most fallacious of human evidence. Never was there a pretender so ignorant, or a medicine so vile or so inert, that could not accumulate thousands of cures, from hypochondriacs, feeble-minded people, charity patients, and accommodating friends, to say nothing of downright forgery, which produces most of the published certificates.

The formula for medicinal bitters in general runs thus: Take of cheapest whisky, an indefinite quantity; of any bitter vegetable, herb, flower, root or bark, q. s. Mix, and flavour with anything or nothing. Put in bottles and employ an expert liar to write labels and certificates. Present a few bottles to editors and clergymen of taste. Advertise

largely and sell for five hundred per cent. above cost of material.

This subject is highly important in its moral relations. Medicated bitters are not used like ordinary medicines, in occasional doses. They are repeated day after day, habitually. Composed, as they are essentially, of alcohol, they lead directly, and often irresistibly, to intemperance. The entire spawn of medicinal "Bitters" are little more than lures to drunkenness. It is surprising that respectable apothecaries sell and distribute them—more surprising still that they originate and invent them. The traffic in medicated "Bitters" is a fraud and a nuisance, calling for legal restraint.

A number of years ago, an individual coming overland with a company to California, served as cook to the company, and was styled "doctor" on that account. He settled in Calaveras County and laboured as a miner, without success. His attention was then turned to the medicinal qualities of the herbs growing about him, and he came to San Francisco with the idea of making and vending a preparation to be called "Indian Vegetable Bitters," and to contain no alcohol. He fell in with an enterprising druggist of this city, who saw money in the project and embarked in it. At the suggestion of the latter, the "Indian" was struck out, and as the new medicine got sour by fermentation, it was concluded to call it "Vinegar Bitters," and to identify it with the movement against alcoholic drinks. The mountain herbs were thrust aside, and aloes, being a cheap bitter, was substituted. "Nine sick people out of ten," said the druggist, "will be cured by purging." Wherefore the aloes. So the cook became doctor, and the decoction became sour, and "Doctor Walker's Vinegar Bitters" began their career in the newspapers.

At that juncture, I one day opened a new number of the *Pacific Medical and Surgical Journal*, of which I was editor, and found to my amazement and mortification a full page advertisement of this nostrum, with all its pretensions duly set forth. The advertisement had been sent to the printing office and inserted without my knowledge. It did not appear again.

A year or more afterwards, a medical gentleman of St. Louis wrote to me inquiring if I had ever endorsed the nostrum, and stating that every bottle of it distributed in the valley of the Mississippi bore my recommendation. The good "Doctor" Walker, or an equally conscientious coadjutor, had copied from the discarded advertisement his own statement of the virtues of the "Bitters," and credited it to me as the editor of the *Journal*!

Is there no way of protecting society against the array of impostors and impostures which prey on health and life? It is not my purpose to answer this question, nor would it be proper to prolong this article. Various expedients have been proposed—such as prohibiting the practice of medicine or the assumption of the title of doctor without a diploma; requiring all proprietary or patent medicines to have their ingredients printed on the label, and so forth. Hitherto laws for the suppression of quackery have done but little good—at least in America. It is difficult to enforce them, and any attempt to do so on the part of physicians is attributed to sordid motives. But the people, not the medical faculty, have need of the protection. Quacks and quack medicines increase the demand for regular treatment, by creating disease and by training the minds of people to morbid action and their bodies to perpetual dosing. They manure the soil for the growth and accumulation of morbid products. If legislatures determine to interpose the shield of law for the protection of their constituents, certainly we shall not object. But law, alone, is impotent. The evil is too deeply rooted for that remedy. I have more hope of success against the nostrum deluge through an infusion of conscience into the "middle-men"—the druggists and apothecaries who stand between the fountain and its distribution, and irrigate the community with the poisonous flood. By their associations, publications and colleges, our pharmacists are fast elevating their business above the standard

for an apothecary to deal in "Bitters" and other nostrums as to sell grog. But the advertising quacks and impostors are more difficult to manage. Arrayed on their side are the ignorance, prejudice, credulity, and other base elements of character in the common people, and above all the annual subsidy of ten millions of dollars, which enables them to purchase and control the periodical press of America.

# INDIAN MEDICAL NOTES.—No. XXIV.

(FROM OUR SPECIAL CORRESPONDENT.)

SIMLA, August, 1874.

"ON LEAVE."

THROUGH the pelting rain this letter will be carried by runners on foot from Simla to the plains, nearly fifty miles, over lofty mountains, then down deep ravines. From Kalka to Umballa the mail cart will be checked by a swollen river, to be crossed by elephants, and from Umballa to Bombay the road is not clear, for near Saharanpore the line is reported to be damaged by the floods. Such being the case, why write at all? why take the trouble to put together matter on paper which may never reach destination? The answer is very simple. It takes years and years to learn how to describe things, the scribbler hoping to overcome by perseverance many difficulties and objections characteristic of each individual style. To write also even a little involves reading, observation, and research, which may not be altogether valueless in after years. One difficulty is the tendency to be erratic, discursive, frivolous, jerky, disconnected, dragging in extraneous twaddle, besides neglecting the weightier matters of the law. To overcome this may be impossible—to improve is the desire. Last Sunday, at Simla, a sermon was preached in aid of a fund to establish female nurses in Indian hospitals. Formerly, governesses coming out here were bound by heavy penalties to remain single. Love laughs at locksmiths, and the husbands either honourably paid the fine or defied the consequences. Some of the marriage announcements are very quaint, the lady generally described as of great beauty and elegant accomplishments, her age and settlements also published. Will these new nurses marry or get into scrapes? Why should they? At Jubbulpore, Allahabad, Meerut, Delhi, Agra, Mussoree, Kussowlee, and Simla, and other places personally visited, there were spinsters. The other day, however, a dandy of comfortable means travelled many miles from the plains to the Laurence Asylum to get a wife; yet, in spite of fine clothes, gold chain, rings, scented pocket handkerchief, bear-greased locks and killing manner, not one of the girls would take him for better or for worse; so down the hill sadly he returned to bachelor solitude. Will these nurses be able to carry on their priceless profession in this climate in August and September, when malarial fevers prostrate all? In England there was an opposition; there were many difficulties which need not be discussed now, connected with female nursing; the intention was excellent, and doubtless the plan will crop up again as the glorious system of sisterhood emerges from the trammels of ignorance, prejudice, and religious controversy. Everybody knows the story of the blister ordered for the sternum being applied to the buttock, and such like anecdotes. Very few have any conception of the strides and progress of nursing in England. In India the sick soldier and the male native nurse have nothing in common, do not understand each other; when the medical officer, having given all directions, returns to his house, perhaps unfortunately some distance off, the nurse may not zealously minister to the constant requirements of the invalid, who may not be able to conquer repugnance to native cooking, or the smell of the hubble-bubble. The best of food, good wine, bedding, and medicines, may, as said before, be tampered with.

In serious cases a trained European, especially a comrade, is invaluable, provided he is sober, not too young or weakly, or specially susceptible to disease, or an idle, useless barrack loafer, or plausible shuffler. In regiments it is easy enough to have a varied choice, which would be impossible in detachments, or a battery of artillery consisting of 150 men, each one urgently required for guns, horses, harness, stables, guards, saddlery, shoeing, &c.; and, before the point is forgotten, my humble opinion is that no man under twenty-five should work in a forge in the hot weather, when also shoeing should be reduced to a minimum. On first arrival in India the want of morning sleep is a difficulty not easy to overcome, for the mid-day snore after food provokes dyspepsia, leading to visceral disease. Soldiers sleep sometimes at their post on sentry until accustomed to the climate. Charles Lamb declined to be the sun's courtier to attend at his morning levées. "The seeds of sleep and mortality are in us; we choose to linger in bed to digest our dreams." But then he was superannuated, and had no public duties to carry on.

The medical subordinate department, as alluded to before, contains many splendid conscientious men, not to be damned by faint praise; still, the medical officer cannot be too often about the hospital, though the running to and fro under a June sun cannot always be done with impunity. Of the two, intense heat is more tolerable than extreme cold. In my opinion, from the experience of India and Canada, but beyond frost bite and certain sequelæ, the after effects of cold are trifling when compared to hepatitis, remittent fever, heat apoplexy, or dysentery. In hospital here, on each patient's diet-sheet, unless a trumpety simple case, it is not a bad plan in pencil to note down in hieroglyphics the daily prominent points—pulse, respiration, temperature, tongue, night report, skin, urine, urea, excreta, local or special symptoms, heart or chest sounds—all can be done in one line, and neither the patient nor Job-comforting friends can decipher the indications when the tide has turned or the danger more imperatively demands attention. How often cholera and other diseases run riot more in hospital than in barracks! How often, again, the prevention of panic is the prevention of the blaze of pestilence! The doubts concerning female nurses in male hospitals do not apply where their services are required to attend the wives of officers or civilians at their homes, or soldiers' families in hospitals. Ladies state that, in addition to the well-known objections, many of the present nurses charge exorbitantly. Where there is no nurse the husband and the medical attendant must perform many offices never imagined in their philosophy, and unless the doctor knows the language, how is he to direct the female servants? What takes place in a regal harem when a little stranger appears was related the other day, or read somewhere. Drinks of hot milk mixed with rice, pease, ginger, and cloves, are given to the mother, and joyful saloos of artillery or a brilliant blaze of fireworks convey the glad tidings that a son is born. For him, for twenty-seven months, a wet nurse will be engaged, whose food, morals, and conduct will be watched day and night by Argus-eyed sentries. On the ninth day (the delivery-room being purified afterwards on the fortieth) the mother, bathed and dressed to receive visitors, accepts presents of silver and gold ornaments, toys, or a cradle. Then is the child bathed for the first and only time, for a year bodily inunction with oil the daily custom after. After forty days the mother rejoins the family circle. Female children receive but little honour, even amongst the aristocracy. During the great festival of the Mohurram, the Mahomedans, husband, wife, and suckling infant, almost starve, and connubial rites are suspended. It is a period of morbid religious gloom, when interference or contradiction leads to bloodshed, and when, night and day, women, beating their breasts until abscesses are provoked, cry "Hassain-Houssen," or, in the vernacular of the British soldier, "Hobson-Jobson." There are marvellous tales of how the natives recover from surgical injuries or operations—for instance, after amputation at the hip-joint for shark bite. Speaking generally, very little do we

know about the natives, their earnest religion, fidelity, love of land, home and kindred, their kindness to poor relations, and respect for the aged. They will lie, drink, and steal; so do enlightened Europeans.

In the dirty bazaars, hot, foul, and steaming, there may be seen the missionaries reading or preaching to the halt, maimed, blind, paralytic natives, perhaps suffering from stone, goitre, or elephantiasis.

Frail, sickly, care-worn look the ambassadors of Christ—heart-breaking, desponding appears the heavenly work; still they persevere, and the reward comes at the day of rest. No fault of theirs is it that converts somewhat largely figure as prisoners in gaols. The names of Ward, Swartz, Marshman, Carey, and others will never die. Francis Xavier, in 1542, at Goa, lived in a hospital, his associates being lepers or condemned felons.

Henry Martyn, the scrofulous son of a Truro miner, after a life of bodily pain, vexation, and disheartening opposition, died at the age of thirty-one. On one occasion, whilst the thermometer rose from  $112^{\circ}$  to  $126^{\circ}$  in a tent, his sufferings were extreme. Receiving an income of £1,000 a year, his heart ever yearned for his old Cornish love, Lydia Grenfell, at Marazion; but most wisely it was ordained otherwise: his lungs and liver apparently were diseased on first arrival. The year of his death, 1812, Adoniram Judson, of Massachusetts, another missionary, then aged twenty-four, was forbidden even to land, much less to preach in Calcutta. Afterwards, for two years, the Burmese kept him chained in a loathsome dungeon; his wife all but died of spotted fever, and the children (one unvaccinated) were attacked with variola. After his release Mrs. Judson's fortitude gave way, and she died with these words on her lips—"I am quite well, only weak," very characteristic of enteric fever. After seven years of widowhood Judson married the widow of a consumptive missionary, and for eleven years enjoyed domestic happiness, increased by children. After thirty years' good service in a tropical climate his wife's health compelled him reluctantly to leave, and at St. Helena again he became a widower. On landing at Boston great was the enthusiasm; evidently, Judson's piety, faith, zeal, and perseverance were all fully recognised. Then, aged fifty-seven, his step was elastic and energetic, and his hair but slightly grey. Very soon again he married for the third time, on this occasion a young lady of literary accomplishments, and to Burmah he returned to work as a missionary, also to complete a dictionary. Three years afterwards, compelled by fever and bronchitis to leave, and nursed by his invalid wife, attended professionally by the captain, he died on board ship, and in the deep blue Indian ocean he sleeps until the sea yields up her dead.

On the subject of Indian gaols, just one word here, to say that at Meerut there are two prisons, one lodging 877, the other 363; the mortality in 1872 being 104 and 46 respectively, increased by cholera, dysentery, diarrhoea, and respiratory affections, attributed greatly to the rise of the level of the sub-soil water throughout the district, thanks to canals. As regards the native army at Meerut the general health appears to be excellent, although phthisis, atrophy, and anæmia are somewhat prominent; the record for 1872 shows but 14 deaths out of a strength of 846; the layer of sandy soil overlying the clay very possibly protecting the native lines, as written before. It may not be true so many fabulous silly stories are palmed off on Anglo-Indians; they do say that natives are let out of prison at stated intervals to increase their families. Lord Amberley should look to this. In an old note-book, now mislaid, occurs a list of individuals who died untended on the field of battle—for instance, the wounded at Agincourt and elsewhere, Picton at Waterloo, Lord Hardinge out here (I think); also instances of fractures, dislocations, strangulated hernia, retention of urine, complicated labours occurring at a distance from professional aid crop up at home as well as abroad. The other day an official of position, a stout unhealthy subject, was seized with apoplexy in a solitary district seventy miles beyond Simla on the Thibet road. His companion, adopting the only means

sends messengers on foot over the mountains to Simla for assistance. Although on leave, and there are two civil surgeons here, this duty (besides the care of several patients, mostly requiring pernitrate of iron for bill diarrhoea) devolved upon yours truly. It was a drizzling wet morning, the mountains and ravines obscured by cotton-wool mist; when unable to walk or ride through slippery slush I was dodged along Guy Fawkes fashion, provided with food, medicines, and appliances; and thus, over the narrow ledges, at an elevation approaching 9,000 feet, rushing from one desolate hut to another, twelve miles off, where coolies are supposed to be found, was the road traversed. "Supposed" is a convenient, elastic, oft-repeated term in India. With the greatest difficulty, imploring, storming, bribing, shouting up the hills and down the dales for men, could fifty-four miles be achieved on a Wednesday and before mid-day on Thursday, the night spent at a rest-house, as the black darkness and the want of coolies stopped progress, sometimes through forests on the brink of awful precipices aggravated by landslips. In the shade in the plains that day the temperature was  $105^{\circ}$ ; in the railway carriages at one place  $108^{\circ}$  compared to  $55^{\circ}$ , as recorded by an accurate thermometer on the road to Nagkanda. The respiration of the horribly smelling stretcher-bearers was also  $55^{\circ}$ , whilst the heart and pulse of Guy Fawkes worked oppressively slow. In the rest-hut at night, whilst shivering with cold over a fire of logs, the danger of chill, the cause of hepatic abscess supplied some notes for a future paper. Bound on such an errand, eager to push on, the anxious mind in no mood to appreciate even Paradise, still, in the intervals between the drenching showers the patient was forgotten in the exquisite scenery forced on attention. Imagine the most triumphant paint-brush effort of Beverley at Drury Lane in those gorgeous sylvan transformation scenes to form the faintest conception of the effects of the sun softly playing on clouds, sky, lofty mountains, and deep ravines, relieved by neatly cultivated slopes of green and gold, or the pines, oaks, cedars, sycamores, the fir-cones of orange or purple bronze, or the red rocks shaded by velvet moss or curious stoncrop, the dark crevices filled by rare delicate ferns close to pleasant-sounding waterfalls, pretty red and white wild roses, anemones, bluebells, honeysuckle, heliotrope, sweetbriar, jasmin, and clover perfume the rarefied air. Even some of the damask flowers of the rhododendra (which poisoned, according to Xenophon, the soldiers, the honey also refused by the Romans) here and there flourished even in June. The ripe wild strawberries, the yellow raspberries looked very tempting. Hazel, bamboo, horse-chestnut, wild cherry, plum, peach, and walnut-trees—some were in fruit, others blazing with blossom. Green parrots and variegated butterflies alone showed themselves; nor did the glowworms in the evening sparkling like diamonds help to lead the way. The sun grandly set at 7, a few stars twinkled soon after; at 9 it was pitch dark, when one lantern very feebly just prevented a fall down the abyss, for the path is entirely unprotected; and many an accident, even in broad daylight, happens on the Himalayas. Most unfortunately, my arrival was too late; indeed, the history of the case left no hope, had the patient even been in a hospital surrounded by the Faculty. I cannot give particulars for a very obvious reason, as the *Medical Times* once pointed out we cannot be too careful not to individualise cases excepting in courts of law or in after years. In the army, also, we cannot be too careful to remember that we doctors are the paid servants of the State, bound through thick and thin our superiors to support, and to tell no tales out of school. In this spirit the wish and intention is to carry on these "Notes," just giving personal experience and dotting down things which appear curious or of professional utility. At Nagkanda there is a glorious panorama of the snows, which a tourist with nothing on his mind would intensely enjoy. After all, thinking over Killarney, Loch Katrine, Windermere, Snowdon, what lovely spots there are in the old country, and, as said before, so far, what beauty can compare with Niagara, changeless as time, old as eternity!

## Hospital Reports.

### ST. VINCENT'S HOSPITAL, DUBLIN.

DR. MAPOTHER'S WARDS.

Clinical Clerk, Mr. C. E. GEOGHEGAN.

#### *Oxalate of Lime Calculus—Lithotomy—Urethral Micturition re-established on Seventh Day.*

PATRICK M., æt. 7½ years, was admitted for the following symptoms, which had begun about a year since: Pain at the end of the penis and in the perineum, which latterly was of the most intense character, incontinence of urine, and occasionally the passage of a few drops of blood. An increased cloud of mucus was the only abnormality in the urine. On sounding, a most distinct, almost metallic click, was heard, and from this circumstance and the great severity of the pain the stone was judged to be of the mulberry kind.

On August 12th lateral lithotomy was performed, the only trouble being the action of the bowels during the operation. The boy was purged with castor-oil the previous day, and two hours before the operation eight ounces of water were thrown up the rectum. An hour afterwards, finding this had not come away, Dr. Mapother injected six ounces more, but all was retained, notwithstanding the utmost efforts of the patient, and the introduction of a tube for several inches up the rectum before and after he was chloroformed.

Just as the first incision was being made a large quantity of water and of indigestible matters, fruit skins, &c., were ejected.

The bleeding was most trifling, and no tube was placed in the wound. From the 22nd hour to the 40th the urine flowed through the penis, then for the next five days through the wound, the swelling of its edges having lessened.

From the seventh day micturition was solely performed through the urethra, the act was under control of the patient, and the stream was thrown a few inches beyond the penis. Two drachms of castor-oil were given on the fifth day, and the bowels were freely moved three hours afterwards.

From the tenth day the boy was out of bed, and on the 19th the wound was healed.

The stone (which is now in the College of Surgeons Museum) is of a rounded form, with twelve sharp spicules about two lines in length projecting, it is two and a quarter inches in circumference, weighs sixty grains, and is wholly composed of oxalate of lime.

The causation of calculus being, and its comparative infrequency in Ireland being subjects of much interest, Dr. Mapother procured the following information concerning the patient's circumstances: He had always lived in Charlemont Street, had been suckled by his mother for sixteen months, and had never drank any water but that of the Vartry, which contains only a grain of lime in the gallon. The only peculiarity about his feeding was that he was fond of sorrel, which he often gathered and ate in large quantities. This plant contains oxalates plentifully, and they appear in the urine after it is eaten. Sorrel is eaten freely by herbivora, and the oxalate of lime is a common calculus with them. His parents, three brothers, and two sisters, were always remarkably healthy, and their hygienic conditions were far above the average of those in like position.

THE *Wiener Med. Presse* says that Prof. Lebert has determined to resign his chair in the University of Breslau and seek in Switzerland (Bex) that rest from his indefatigable labours as teacher, author, and practitioner, which has hitherto been denied him. Prof. Biermer, of Zurich, has been recommended for his place.

## Transactions of Societies.

### THE NEW SYDENHAM SOCIETY.

THE sixteenth annual meeting of the New Sydenham Society was held at Norwich on Thursday, August 13th, Dr. Waters (Chester) being in the chair. The ballot having been taken, the following officers were declared duly elected for the ensuing year. It was moved by Dr. McIntyre (Odiham), and seconded by Mr. Clubbe, of Lowestoft, that the report and balance-sheet, as presented by the Council, being satisfactory to the meeting, be printed for distribution as usual. Mr. Mason, of Bath, moved a vote of thanks to the officers for the past year, and after some formal business, the meeting concluded. Subjoined is a list of the officers elected:—

#### PRESIDENT.

Cæsar H. Hawkins, F.R.S.

#### VICE-PRESIDENTS.

Alfred Baker, Esq. (Birmingham).	*Hermann Weber, M.D.
E. R. Bickersteth, Esq., (Liverpool).	*J. S. Bristowe, M.D.
*Prescott G. Hewitt, Esq., F.R.S.	*Edward Copeman, M.D. (Norwich).
W. D. Husband, Esq. (York).	J. Matthews Duncan, M.D. (Edinburgh).
Sir James Paget, F.R.S. Bart.	*D. Embleton, M.D. (Newcastle).
T. B. Peacock, M.D.	*Edward Long Fox, M.D. (Bristol).
A. P. Stewart, M.D.	George Southam, Esq. (Manchester).
Sir Thomas Watson, M.D., F.R.S., Bart.	W. Stokes, M.D., F.R.S.
C. J. B. Williams, M.D., F.R.S.	

#### COUNCIL.

James Andrew, M.D.	*W. Price Jones, M.D. (Surbiton).
Warburton Begbie, M.D. (Edinburgh).	J. C. Langmore, M.B.
W. H. Broadbent, M.D.	*Joseph Lister, F.R.S. (Edinburgh).
Charles Brooke, Esq., F.R.S.	*Alfred Meadows, M.D.
T. Bryant, Esq.	G. H. Philipson, M.B. (Newcastle).
Thomas Buzzard, M.D.	*Henry Power, Esq.
Robert Ceely, Esq. (Aylesbury).	*W. O. Priestley, M.D.
W. Cholmeley, M.D.	W. Roberts, M.D. (Manchester).
T. B. Crosby, Esq.	James Russell, M.D. (Birmingham).
Thomas M. Daldy, M.D.	Leonard W. Sedgwick, M.D.
J. Langdon H. Down, M.D.	Septimus W. Sibley, Esq.
Dyce Duckworth, M.D.	*Thomas Sympson, Esq. (Lincoln).
Robert Dunn, Esq.	T. P. Teale, Esq. (Leeds).
C. Hilton Fagge, M.D.	William Turner, M.B., F.R.S.E. (Edinburgh).
J. Fayer, M.D.	
*C. J. Hare, M.D.	
T. F. Grimsdale, Esq. (Liverpool).	
*John Hamilton, Esq. (Dublin).	

(Those marked with an asterisk were not in office last year.)

#### TREASURER.

W. Sedgwick Saunders, M.D., 13 Queen St., Cheapside, E.C.

#### AUDITORS.

E. Clapton, M.D. | S. Fenwick, M.D.  
F. M. Corner, Esq.

#### HONORARY SECRETARY.

Jonathan Hutchinson, Esq., 4 Finsbury Circus, E.C.

The report shows the financial condition of the Society as highly satisfactory, there being more than a thousand pounds in hand, in addition to a very valuable stock of books. The principal works which the Society has now in progress are its Atlas of Skin Diseases, which it is intended to continue for some years longer; its Retrospect of Medicine and Surgery, which appears biennially, and a new and revised edition of Mayne's Lexicon, which is in course of preparation. The latter is referred to as follows in the report:—

The progress of the Society has been satisfactory during

fluenced by the violent opposition to improvement which emanated from the Dublin grinders, and from some of the examiners, and an active minority of its own members, and had conceded, in deference to this opposition, a further continuance of the old system, and that system was, at the time of the visitors' report, practically, if not legally, the law of the College. The Visitors, the Medical Council, and the Medical Press, may be congratulated upon the immediate outcome of the strong censure to which the College has been subjected, and the Council of the College deserves credit for having shown a praiseworthy readiness to acquiesce in the views of the visitors. It has been ordered that at the very next examination in November, important reforms, in accordance with the visitors' suggestions, and with the reformed scheme already adopted, should be introduced. The written examination will occupy four hours on a day separate from the *viva voce*, and in the final examination separate days will be given to writing, *viva voce*, clinical examination, and operative surgery, all which alterations are, so far as they go, most excellent emendations, and, when carried into effect by a thoroughly honest method, will go far to make the examination what it ought to be, and to relieve the College from the stigma which a few obstructionists have brought upon it.

It will be observed that the Council does not concur with the visitors as to the method of examining in operative surgery and clinical examination. We refrain from expressing any opinion on these points, because we really think that variations in method are of little moment so long as there is an intention on the part of the Court to make the examinations efficient and reliable tests of the knowledge of the student. If that intention exist, it may be satisfactorily carried into effect by any method, and we feel confidence that the Council will never again permit any part of their examination to be transacted as a sham, which experience assures us would be unhesitatingly exposed by the visitors on the first opportunity.

The Council of the College differs from the opinion of the visitors that there should be a conference of examiners before the passing or rejection of a candidate is decided. They say :—

As regards the suggestion that there should be a conference between the examiners in reference to the value of the marks to be awarded to each candidate, this, in the opinion of this Council, would be most undesirable, as they are strongly of opinion that each examiner should feel himself quite independent and unfettered in forming his estimate of the professional attainments of each candidate. In exceptional cases, however, it is allowed their examiners to hold such conferences, and the visitors themselves, at p. 136 of their Report, mention an instance where such a conference did actually take place.

We adopted strongly the opinion of the Council, and we maintain that the impartiality of the examination hangs upon the fact that the examiner in giving his mark is entirely unaware whether he in passing or rejecting the candidate. Sooner or later a subsequent conference will inevitably lead to an improper tampering with the honest verdict previously arrived at, and will introduce into the result the influences of favouritism, undue severity, or weak-minded lenity.

None of the offences of the College against the examination creed of the Medical Council have brought upon its devoted head so violent a storm of reprobation as the

refusal to hand the candidates' written papers into the custody of the visitors. There can be little doubt that it was here that the shoe pinched many of the members, and aggravated their indignation against the examinational errors of the College. In reply to the remarks of the visitors on this subject, the Council says :—

The grounds which actuated this Council in declining to accede to this unusual request, the adoption of which course, they regret to observe, has been made the occasion for the expression of much hostile feeling against this College, were :—

I. That it was contrary to both the custom and invariable practice of this College to retain or preserve the candidates' written answers after their inspection by the examiners.

II. That at the former visitation of the examinations of this College, conducted by an eminent member of the General Medical Council, no demand was made to be allowed to remove from the hall the written answers of the candidates.

III. That this Council were not aware of any resolution of the General Medical Council authorising the visitors of examinations to demand possession of the written papers.

IV. That this Council were not aware that any other examining body had afforded a precedent for surrendering to the visitors after the termination of the examination the written answers of candidates.

While, therefore, this Council will always be happy to afford every facility for inspecting, in the hall of the College, by authorised visitors, the written answers of candidates, they must continue to regard these answers in the light, more or less, of privileged communications, and not documents which, in any fairness, they can permit to be exhibited outside the College, and possibly printed and published. This Council are, in fact, strongly of opinion that, were they to allow such a course to be adopted, it would be little short of a breach of faith on their part to successful candidates for the diploma of their College. Neither can they see what possible advantage can be got from the publication of the written answers of rejected candidates; and they think that it is hardly a function of the College to add such exposure to the disgrace of a rejection.

Although we cannot assent to all that the Council says we feel that there is a great deal of force in their defence. We are disposed to regard the reprinting of the disgraceful, answers of rejected candidates, as was done by the visitors in their last report, as an unfair and inexpedient use of the written papers, which the College Council is justified in resisting. It is the proper function of the visitors to pass a verdict on these replies; but we are not disposed to think that the publication of these errors *in extenso* is a justifiable proceeding.

As the result of the entire facts which have arisen out of the visitation, we are bound to say that a great benefit has resulted, not only to the profession and the Medical Council, but to the Irish College of Surgeons itself, and we do not hesitate to say that the system of visitation, in which no one had previously any confidence, has acquired a powerful force in the direction of reform of examination. We are very glad to find that the Irish College of Surgeons has had the good sense to take to heart the severe lesson which it has received, and has at once and cheerfully yielded to the plainly just view expressed by the visitors.

#### THE CLUB SYSTEM.

CONTRACT doctoring has within the last week received an interesting and valuable elucidation at the hands of Sir Edward Kerrison, of Oakley Park, near Grantham, who has published some instructive statistics of a "Self-aid Labourers' Medical Club," which has been worked in the local union. The club at Grantham has no fewer than

4,577 subscribing members, besides honorary members, mostly proprietors. The annual rate of payment by subscribing members is, for each person above 16, 2s. 6d.; under 16, 1s. 6d.; under 13, 1s. No extra payment is required from families exceeding five in number. Each midwifery case is charged 6s. The last report shows that nine medical men were engaged, and that they received £689 in the year, or an average of about £76 10s. each. The subscribing members may choose any of the doctors on the club list as their attendant, but must consult the same medical man for a year. If unable to attend at the surgery, the patients are visited at their homes.

Sir Edward Kerrison claims that this club has in great measure supplied the place of parochial medical relief in the neighbourhood, and has thereby effected a considerable reduction in the medical relief expenditure of the union, to which its operations are confined. He points out that, as compared with four other neighbouring unions, the average annual cost per head of the population in the Grantham Union for medical relief is much lower than in the others, being 7s. 9d., against 11s. in one of the others.

These statistics are very cogent to the club question, which is at present one of the most important which agitates the medical profession. Assuming that they prove as much as Sir Edward Kerrison deduces from them, they prove that a very large proportion of the artisan population who in other places obtain medical relief at the public cost are capable of and willing to pay for such relief an amount which, taken in the aggregate, is considered to be reasonable and acceptable remuneration for medical advisers. It is not our function to assess the actual value of the advice and medicine which is furnished at the rate of 1s. per head per annum, nor to form a guess at the probable extent of the midwifery services which are rendered night or day for 6s. It is sufficient for us to be assured by Sir Edward Kerrison that the value given for their money is considered by the "labourers" of Grantham to be sufficient, and to enjoy our own certainty that the services rendered cannot possibly be lower than the payment. It is certainly something gained if the workhouse applicants for medical relief have been converted, by means of this organisation, to the habit of paying for the physicking which seems to be one of their necessities of life. We experience only one apprehension, and that is that the "Labourers' Union may include within its fold a large sprinkling of small farmers and independent shopkeepers, who by its means acquire the advantage (such as it may be) of shilling-a-year doctoring and six-shilling midwifery. In such organisations the line of demarcation is never too tightly drawn, and it may be that this union is actually doing more harm than good by semi-pauperising a class who might otherwise prefer to secure the attendance of their own independent medical adviser.

#### THE INQUIRY AT NEWMARKET.

THE investigation which was held last week into the conduct of Dr. Meade and the circumstances attending the outbreak of small-pox in that town terminated on Saturday last, the Commissioners, as is usual, reserving judgment until they report to the Local Government Board. Dr. Meade was charged at first with having let four weeks

elapse after an outbreak of small-pox before commencing operations, and then devote half an hour to the vaccination of a whole workhouse (including infirmary men's and women's wards and the school), with one lancet, only once charged with lymph.

The accusations investigated on Saturday were—

1. That he knew of the filthy condition of the small-pox patients in the workhouse hospital, and failed to draw the attention of the master to the facts. 2. In entering his attendance upon the patients suffering from small-pox in his medical relief book visits are said to have been made in almost every case for days after the removal or death of the patient. 3. Entering extras, ordered, after weekly account closed. 4. That he expressed his willingness to give a certificate for the removal of George Jeffery, aged 72, to the Heath Hospital. On the 19th of August Mr. C. F. Grey remarked that the man was dying. He would be dead in three hours. Inspector W. Lamb said, "Let us not get into trouble about him if there is any doubt, or, probably, some of us might be charged with manslaughter." Dr. Meade is alleged to have then said, "You take him and I will give you a certificate. If the man dies on the way you will not be such d—d fools as to keep him there; bring him back and we will give him a decent funeral; not that I want to shorten the old man's life, but he has lived quite long enough." Jeffery died the same evening at nine o'clock, about five hours after this consultation.

While the decision of the Commissioners is pending we cannot, of course, enter upon the discussion as to whether the evidence proves these charges or not. We believe we may, without injustice to Dr. Meade, say, that from whatever circumstances, the epidemic of small-pox at Newmarket was not dealt with with any energy or vigour, or apparently with any appreciation of the alarming nature of the epidemic.

We sincerely trust that the Commissioners will not find it necessary to declare the medical officer guilty of conduct so inhuman as that charged against him, for, if they do, there will be no alternative but to deal with such an officer with severity, and his condemnation will inevitably reflect upon the *morale* of the profession, and imperil public confidence in the existing system of medical relief.

## Notes on Current Topics.

### Statistics of Lunacy.

THE Twenty-eighth Report of the Commissioners in Lunacy has appeared. The statistics show that 62,027 lunatics were registered on the 1st of January last, indicating an increase of no less than 1,731 persons as compared with the register of last year. Of the total number 31,371 are accommodated in county and borough asylums, 2,772 in registered hospitals, 4,713 in licensed houses, 358 in naval and military hospitals and the Royal India Asylum, 520 in the State criminal asylum, 15,018 in workhouses, 436 as private single patients, and 6,839 as outdoor paupers. During the last ten years the average annual increase of lunatics has been 1,723 persons, and in the above classification those in workhouses include the inmates of the metropolitan district asylums at Leavesden, Caterham, and Hampstead. A total of 32,878 pauper patients were, on the 1st January last, detained under statutory orders and certificates in asylums, hospitals, and

licensed houses. Two new tables of statistics are added in this report, one of which shows the actual increase or decrease of pauper lunacy in the several union counties as compared with the previous year, and the other gives for the last ten years the annual averages of the admissions, recoveries, and deaths in the several county and borough asylums and hospitals. The statistics of the Commissioners do not include all lunatics, imbeciles and idiots in England and Wales, for, according to the census of 1871, 69,019 such persons then existed, whereas the returns made to the Commissioners for the 1st of January preceding showed but a total of 58,060 persons. Of cases occupying county and borough asylums, the recoveries, as compared with the total admissions, were in the proportion of 33·95 per cent., or 2 per cent. below the average of the last fifteen years, the mortality being also somewhat lower. It is satisfactory to know that, in consequence of the recommendations of the Commissioners, the proportion of post-mortem examinations to deaths has, during the past four years, risen from 40 to 61 per cent.

### Dr. Whitmire, U.S., on Criminal Abortion.

DR. JAMES WHITMIRE (*Chicago Medical Journal*, July, 1874) read a paper on the above subject before the Woodford County Medical Society, at Eurek, U.S.

According to Dr. Whitmire, there seems to be a growing indisposition on the part of American females, married or unmarried, to bear children. The special crime he speaks of "is not confined to any particular class or condition of life—it belongs to, and is practised by, the married and the unmarried, the rich and poor, the learned and the unlearned."

Besides those females who promote abortion upon themselves, there are professional abortionists of both sexes in all the considerable cities of the United States, who, for a consideration, undertake to produce abortion in any case presented to them without asking any questions. This business is carried on to a great extent, and both women and men knowing these things and the probable certainty of relief with but little immediate danger, are more disposed to be loose in their habits than they otherwise would be, because, with the unmarried, in cases of accident, they are enabled to get rid of their encumbrances with but little or no risk of their shame being published.

Some professional abortionists, it seems, both male and female, claim a membership in the profession of medicine, and do a very considerable lucrative practice; avarice is their besetting sin: but professional men and women who are, in fact, educated and qualified in their calling seldom or never engage in this crime against Nature; they have too much professional pride to be bought with gold, or to be influenced by sympathy to be engaged in such practices.

As to the professional abortionist, he and his business are generally known by the lewd of both sexes for miles around; and they are also known to one another in the different cities, so that if a case is likely to be too close at home for complete safety to all parties the victim is sent to the next bloody station, where the operation is performed, and a reciprocity of iniquity is kept up.

It appears, also, that drastic cathartics are largely sold,

called *Professor Bombasticus' Female Pills*, throughout the States, and are much resorted to. "You may step into any country or city drug-store in the State of Illinois and procure, without the prescription of a physician, any one of these reputed abortion-producing medicines, not excepting ergot, bark of the root of the cotton-plant, oil of savin, &c."

"At this moment," says Dr. Whitmire, "I can recall to memory many females who, I have reason to believe, short of absolute knowledge, have frequently produced abortion on themselves, sometimes by violent purgation, lifting, jumping, and even with a blunt probe or uterine sound, either of which they have learned to use by reading obscene books published expressly to impart such information." These are not isolated cases; such exist everywhere, in every village and neighbourhood. This iniquity is not confined wholly to our populous cities, but is practised all over the country to an alarming extent.

"This iniquitous profligacy of human life," says Dr. Whitmire, "and prevalent violation of the laws of our being is one great cause and reason for so few native-born children of American parents according to the number of young married people and in comparison with those of other nationalities around us. This, too, accounts for so few household gods to be worshipped by American parents that would make home happy and overflowing with joy and gladness. This, too, is one of the reasons why we are fast losing our national characteristics and slowly merging into those of our foreign population, who, according to the United States statistics of 1870, are rearing 50 per cent. more children, according to their number, than Americans are doing."

### Anti-vaccinators.

THE difficulties of legislating for the million are amply demonstrated by the account of a demonstration at Gainsborough of some 3,000 people against one of the most useful and important measures ever introduced, notwithstanding cheap education, school boards, and the schoolmaster being abroad—evidently he has not made much impression on the intelligence of the masses; let us hope the application of prison discipline will in the end bring about more practical results. It appears that a workman named Aisthorpe was sent to prison for fourteen days for refusing to have his child vaccinated. After serving the term he was met, upon leaving prison, by some two or three thousand persons, and received an ovation which lasted some minutes. His wife and family were placed in a conveyance, the horse taken out, and the vehicle joined the procession, drawn by his fellow-workmen, the band playing "See the Conquering Hero Comes." In this order the procession passed through several streets to the market-place, where a public meeting was held. A Mr. Wm. Durst presided, and in opening the proceedings thanked the meeting for coming forward to welcome their townsman after his period of incarceration, to which he had been sent for no crime, but for refusing to have the blood of his (Aisthorpe's) child poisoned. A Mr. Johnson, of Lincoln, begged to move the adoption of a memorial from "the people of Gainsborough in public meeting assembled" to Mr. Disraeli and the President of the Local Government Board, praying

for the entire repeal of the Vaccination Acts. The memorial was carried *nem. con.* amid tremendous cheering. Mr. A. Robinson then stepped forward to present his "shopmate," Aisthorpe, with a purse of money which had been subscribed chiefly by working men in recognition of his self-sacrifice in going to prison. Aisthorpe briefly replied, thanking all present, and expressing a hope that no more fines would be paid, but that they would band themselves together and go to prison as he had done. The new Act alluded to by the chairman was then produced, and after being read was burnt amid the cheers, hisses, and groans of the assemblage. The chairman asked the meeting to disperse quietly, which they did after another round of cheering.

### The Sanitary State of Lincoln.

THE City of Lincoln appears anxious, through its representatives, the guardians, to remedy the present unsatisfactory state of things as regards sanitary matters and its consequent unhealthiness. But, as is unfortunately the case, when money is to be spent for some great public improvement, opinion is divided as to the mode of expenditure, and whether it shall be spent at all. For instance, at the Council meeting last week one member said that the health of the city was not nearly so bad as was represented, the death-rate being only 19 per 1,000 of the population; there was, therefore, no need to be in a hurry to ruin the ratepayers by carrying out a scheme about the efficacy of which they were uncertain. On the other hand, the Lincoln papers maintain that Alderman Maltby is entirely wrong, the death-rate in the city averaging last week the enormous figure of 46 per 1,000, being in fact the most unhealthy in the United Kingdom. Certain it is that both cannot be right, and if Alderman Maltby be wilfully misstating the case, we can conceive of nothing more culpable than for a public man to betray his trust for the cheap popularity of the masses.

### Charge of Libelling a Medical Man.

At the Bridgwater Police Court, on August 31, Mr. G. Pain, solicitor, of Bridgwater, was charged with having unlawfully published certain defamatory libels concerning Mr. Charles Forbes Buchan, a medical man practising in that town. Some months ago Mr. Buchan was charged by Mr. Pain with obtaining £200 from him under false pretences; but at the assizes Mr. Justice Lush directed the jury to return a verdict of acquittal. Since then, the defendant has addressed letters to the complainant and his father, and to Dr. Baxter Langley, containing, it was alleged, libellous matter. One effect of these communications had been seriously to affect the health of the complainant's father, whose son had been referred to as a "lying thief," "depraved wretch," &c. The defendant was committed for trial at the next assizes, being admitted to bail in his own recognisances of £200, and two sureties of £100 each.

### An Italian Bequest to Medicine and Science.

THE *Allgemeine Wiener Zeitung* publishes a statement that a larded proprietor, who died here, has bequeathed all his property to the three academies of science of Lon-

don, Vienna, and Paris, and to the Vienna general hospital. The will was executed in the year 1856, when Milan was still under the Austrian dominion. At that time the property of the testator amounted to about 825,000 livres. A codicil to the will ordered this sum to be divided into three equal parts among the three academies already mentioned, on the condition that two prizes be offered yearly for *concours* examinations, and with the further condition that the prizes in Vienna should only be awarded to German Austrians. The codicil also provided that all the increase of the property above this sum should fall to the share of the Vienna general hospital. Now, at the death of the testator, his property is found to be worth 1,800,000 francs, so that the hospital is the chief legatee of the deceased. All movable property, in particular his valuable library, he left to the Vienna Academy of Sciences. It is said that this will will be contested, on account of the mental incapacity of the testator.

### Hydrophobia—a Simple Precaution.

DR. LOCKE JOHNSON suggests that in cases of injury from cat or dog-bite—whether the animal be in a rabid state or otherwise—a roller (garter, piece of cord, handkerchief, &c., will answer the purpose in an emergency) should be at once tightly applied above and below (and also close to) the seat of injury, and should not be removed for some hours subsequent to canterization. When the rollers cannot be effectively employed on account of the position or seat of the injury, compression *all round* the wound should be made by firm pads, pieces of card-board perforated, gutta-percha, or other substances, and the security of such compress maintained by means of a roller drawn tightly over and fastened. Thus the tendency to absorption of the virus will be lessened, and the pain usually produced by canterization—especially if the wound or wounds be extensive—very much decreased.

### Comparative Healthiness of English Watering-places.

FROM the Registrar's returns for the districts or sub-districts containing, and approximately representing, the principal English watering-places, we extract the following results for the 10 years, 1861-70:—In the sub-district of South Bersted, containing Bognor, the annual mortality averaged only 15·3 per 1,000 persons; in Folkestone, 16·4; Prittlewell, containing Southend, 16·6; Eastbourne, 17; Ilfracombe, 17·1, and the same in Worthing; Isle of Wight, 17·2, and the same in Tunbridge Wells; Ramsgate, 18·1, and the same in Penzance; Tenby, 18·2; Harrogate, 18·4, and the same in Wallasey sub-district, containing New Brighton; Ottery St. Mary sub-district, containing Sidmouth, 18·6, and the same in Littlehampton, and also in Deal and Walmer; Banwell sub-district, containing Weston-super-Mare, 18·7, Torquay, 18·8; and the same in Teignmouth and Dawlish; Dover, 19·2, and the same in Lowestoft, and Creuddyn, containing Llandudno; Hastings and St. Leonards, 19·4, and the same in Leamington; Matlock, 19·6, and the same in Exmouth and in Dartmouth; Cheltenham, 19·9; Clifton, including part of Bristol, 20; Lyme Regis, 20·2, and the same in Hanley Castle sub-district, containing Malvern; Weymouth, 20·3;

Herne Bay, 20·5; Beaumaris, 20·7; Buxton, 20·8; Poulton-le-Fylde sub-district, containing, Blackpool and Fleetwood, 21·2; St. Asaph sub-district, containing Rhyl, 21·9; Margate, 22, and the same in Brighton and Hove; Yarmouth, 22·5; Aberystwith, 22·7, and the same in Bangor; North Meols sub-district, containing Southport, 23·1; Bath, 23·3; Scarborough, 23·4; Whitby, 24·2 per 1,000. In order to compare statistics compiled by the same authority during 1874 with those of the ten years given above, the following will give us an approximate estimate:—It was in many places less, often materially less, than in the 10 years 1861-70:—In South Bersted (Bognor) it was only 14·9; in Worthing, only 12·9 per 1,000; Isle of Wight, 16; Tunbridge Wells, 16·4; Ramsgate, 13·6; Tenby, 16·7; Harrogate, 17·9; Ottery St. Mary (Sidmouth), 14·9; Littlehampton, 11·7; Deal and Walmer, 17; Torquay, 11; Lowestoft, 13·8; Dover, 17·7; Leamington, 16·4; Matlock, 18·1; Cheltenham, 15·3; Clifton, 17·9; Hanley Castle (Malvern), 11·5; Herne Bay, 19·8; Beaumaris, 15·3; Buxton, 13; St. Asaph (Rhyl), 19·1; Margate, 21·1; Brighton with Hove, 16·6; Yarmouth, 21·9; Aberystwith, 18·3; Bangor, 18; Bath, 19·1; Scarborough, 15·5; and Whitby, 20·3. These returns show an improvement on those for 1861-70. Other places do not maintain the 10 years' average. In the second quarter of 1874 the annual rate of mortality in Folkestone was 20·5 per 1,000; in Prittlewell (Southend), 21·5; Eastbourne, 17·6; Ilfracombe, 20·5; Penzance, 20·7; Wallasey (New Brighton), 22·2; Banwell (Weston-super-Mare), 19·8; Teignmouth and Dawlish, 22; Creuddyn (Llandudno), 23·4; Hastings and St. Leonards, 19·5; Exmouth, 21·5; Dartmouth, 23·3; Lyme Regis, 31·5; Weymouth, 21·7; Fylde (Blackpool and Fleetwood), 26·1; North Meols (Southport), 24·2 per 1,000. It is worthy of remark that all the nine inland watering-places in the 10 years' list show an improved state of health in 1874; their death-rate in the last quarter ranging from 11·5 to 19·1 per 1,000.

### The Banbridge Waters.

THE waters, nineteen in number, used in the town of Banbridge, have been submitted to analysis by Professor Cameron, of Dublin, who reports unfavourably upon the great majority of them. The solid matters per imperial gallon varied from 1234 grains per gallon to the enormous amount of 120·37 grains. Only one or two of the waters were reported to be of fair quality. The following is the composition of one of the worst:—

Solids per gallon, 120·370 grs. (including albuminoid nitrogen, 0·186 grs.); ammonia, 0·238 grs.; nitrous acid, trace; nitric acid, large amount; sulphate of lime, 25·000 grs.; chlorine, 16·650 grs.

The amount of ammonia and albuminoid nitrogen in this water is at least twenty times greater than is found in pure waters. Nearly all the Banbridge waters are almost as bad as the one above particularised.

### Saw-dust Brandy.

WE have heard of butter made from Thames mud, which extraordinary discovery existed only in the muddled brain of some "knowing-one;" of "high class" port and sherry, whose composition was as much allied to

grape-juice as the moon to green cheese, and which filthy decoction is unfortunately as common in the British market as real grape wine. But what will our readers think of the latest discovery, reported in an American contemporary, *The Clinic*—saw-dust brandy, which a German chemist is said upon good authority to have produced.

We are friends to the temperance movement, says the editor, and want it to succeed; but what chance will it have when a man can take a rip-saw and go out and get drunk with a fence-rail? What is the use of a prohibitory liquor law if a man is able to get the *delirium tremens* by drinking the legs of his kitchen chairs? You may shut an inebriate out of a gin-shop and keep him away from taverns; but if he can become uproarious on boiled saw-dust and desiccated window-sills, any effort at reform must necessarily be a failure. It will be wise, therefore, if temperance societies will butcher the German chemist before he goes any further. His recipe ought not to be made public. He should be stuffed with distilled boards until he perishes with *mania a potu*.

### Small-Pox Inoculation in Ireland.

WE observe that the practice of small-pox inoculation is rife in the county Mayo, and that numerous cases of variola are reported by the medical officers. The parents of children inoculated refuse to reveal the name of the inoculator, and the guardians have accordingly ordered the prosecution of the parents themselves. We hope that we shall have no namby-pamby soft-headedness on the part of the magistrate, but that this most outrageous offence will be stringently dealt with.

THE library of the Obstetrical Society will be closed from the 7th to the 19th of September.

By the will of the late Sir E. Beckett, Leeds Infirmary receives a legacy of £1000, and the Doncaster Infirmary £250.

It is proposed to perpetuate the memory of the late Dr. Bhau Dajee of Bombay by the establishment of an hospital for lepers.

THE Belfast General Hospital has obtained a charter, and will in future bear the title of the Royal Belfast General Hospital.

SCARLET fever is now prevalent in St. George-in-the-East, although the medical officer of health for the district has not reported any deaths.

DR. JOHN DOUGALL will read a paper on the "Science of Disinfection" at the Social Science Congress, which meets at Glasgow in October.

THE trustees of the Cholmondeley charities have made a second grant of £25 in aid of the Royal National Hospital for Consumption at Ventnor.

MR. JAMES LEWIS has been promoted to an inspectorship for the purposes of the Acts relating to the registration of births, deaths, and marriages in England.

DR. ALLEYNE NICHOLSON has been appointed to the Chair of Biology and Physiology in the Durham University College of Medicine and Physical Science, at Newcastle-on-Tyne.

SIR ALEXANDER ARMSTRONG, K.C.B., Director General R.N., made an official inspection of the Royal Naval Hospital at Haulbowline, Queenstown, on Friday, the 4th inst.

THE Registrar-General reports during the week ending last Saturday 5,302 births and 3,380 deaths in twenty-one large cities and towns of the United Kingdom. The average rate of mortality in these towns was twenty-three per thousand.

ON August 18th the foundation of the new Samaritan Hospital, at Belfast, was laid by Dr. Hodges, Professor of Medical Jurisprudence in Queen's College, in the presence of a distinguished company. The foundation of this hospital is due to the liberality of the late Mr. Edward Benn, of that town.

SCARLATINA is still very fatal in Dublin, twenty-two deaths having been registered during the week ending August 22nd, and thirty deaths the preceding week, the highest number this year from the affection. Nine deaths from scarlatina were also registered in Belfast during the past week, and a similar number from small-pox.

THE foundation of a Convalescent Home in connection with the Orphan Working School at Haverstock Hill was laid on August 29th, at Margate. The want of such an auxiliary to the Home has long been felt; as more than one-half the parents of these children had died from consumption, the orphans required special care.

SMALL-POX has been entirely stamped out at Newmarket. It is now nearly a fortnight since the last case, a mild one, was removed; and all the afflicted, both from the town and union, are in the hospital. Active measures have been taken by the Board of Health and Mr. Lamb, sanitary inspector, to purify the infected quarters.

LIEUT. BOYNE, of the 38th Regiment, who a short time ago walked from Aldershot to London in less than seven hours, has just walked from Aldershot to London and back, a distance of seventy miles, within seventeen hours. He started from the officers' mess for London at three p.m. on Wednesday, and arrived at the mess at 7.39 a.m. on Thursday, and appeared to be quite fresh.

A HOME of temporary rest at Harrow for the benefit of trained nurses who are suffering from the effects of overwork is contemplated. It will to a certain extent be self-supporting. A sum of seven shillings a week will be required from each inmate for maintenance; the power of modifying this rate in exceptional circumstances will be reserved. Subscriptions will be received by Miss Catherine Whitehead, Harrow.

THE *Jardin Zoologique* states that a few days previous to the ravages of cholera in Galicia in 1872, all sparrows quitted the town of Przemyśl, and not a bird returned until the end of November, when the disease had disappeared. The same circumstance was remarked in Munich and in Nuremberg. During the attacks of cholera at St. Petersburg and Riga in 1848, in Western Prussia in 1849, and in Hanover in 1850, every swallow and sparrow forsook the towns.

THE corporation of Sheffield, in view of the large proportion of sickness and deaths, caused in the town by the consumption of bad food, has commenced a crusade against suspected tradesmen. On Friday last three of them were summoned by the magistrates. One, a butcher, was fined £80 for exposing for sale eighty pieces of bad meat, some of which were crawling with maggots; a provision dealer was fined £55 for having in his possession eight hams intended for sale and unfit for human food. A fruit dealer, named William Cooper, was also fined £5 and costs for selling rotten pears.

DR. THOMAS BALLARD, late President of the Harveian Society of London, died on September 1st, at his residence, Southwick Place, Hyde Park. He had for some years past been suffering from diabetes, but was able to be present at the late meeting of the British Medical Association, at Norwich. After his return to town, inflammation of the hand, with oedema of the arm commenced, supposed to be occasioned by plugging of veins. Dr. Barclay, Mr. G. D. Pollock, and Mr. Eastes were in attendance, but the suppuration extended, and patient became worse, and gradually sank. He belonged to various medical societies, and will be missed by a large circle of friends and patients.

THE Inspector-General of the French Lunacy Department has published the results he has obtained from a careful study of all the statistical documents he has been able to collect on insanity in France during the years from 1869 to 1872. He has arrived at the conclusion that, although during that trying period for Frenchmen, from 13,000 to 14,000 cases of mental disease were registered, yet the number of patients confined in private lunatic asylums was much below the usual average. A similar fact was observed in 1849, which, taken in connection with the state of things observed by Dr. Lunier, would make it appear that political or social crises, instead of, as is generally imagined, augmenting the number of insane persons, really diminishes it.

THE so-called University of Philadelphia has been again brought under public notice in an inquest held at Nottingham, on the body of a woman named Ellis. A person named John Wilson, calling himself a "doctor of medicine of the University of Philadelphia," had prescribed green hellebore for her, under the idea that she was suffering from erysipelas of the face. As she became worse, Mr. Snell, surgeon, was called in, and found that the patient was suffering from delirium and congestion of the brain, arising from disease of the kidneys. He believed that the patient, if treated properly at first, might have recovered; but he did not think that the hellebore

had actually caused death. The coroner said that he regarded the case as one in which Mr. Wilson had prevented other and better advice from being procured, which might have saved the life of the woman. When Mr. Snell was called in, the woman was dying, but, if his assistance had been obtained sooner, the probability of her recovery would have been greater, and he thought it was to be regretted that Mr. Wilson stepped out of his line of business to give her aid. English laws might be different from American laws, because anyone who was put upon the *Medical Register* in England and was qualified to practise had to pass certain examinations, and the law was strict enough to say that a man could not recover his fees for attendance if he were not on the *Register*. In this instance, Mr. Wilson practised as a regular qualified man when he had not the necessary qualifications. It was to be regretted very much that he attended this case at all, and stepped out of his path as he did. The jury returned a verdict "that deceased died from disease of the kidneys, and the jury regret that proper medical advice was not obtained earlier." The coroner, addressing Mr. Wilson, said that he must be well aware that he had no right to visit the patient and practise as a medical man in England unless he had the proper qualifications.

It was a serious matter, and, if persons died under his attendance, he (the coroner) should feel it his duty to hold an inquest in every case.

### THE FOOD OF PLANTS AND ANIMALS.

PROFESSOR REDFERN read a paper on the "Influence of Food, and the Methods of the supplying it to Plants and Animals," before the Belfast meeting of the British Association, from which we take the following :—

"Plants," he said, "entirely uninfluenced by any but physical conditions, had long since taught farmers, and gardeners especially, that they must not only have abundance of food, but that they must have it in a condition in which they can readily make use of it. In proof of this, he need only refer to the known necessity for the regular use of highly nutritious liquid manure in the cultivation of perfect roses, and to the care the agriculturist had learned to take in the application of the proper kind of artificially prepared manure for each crop, and in its use in a form in which the plant could most easily absorb and apply it. It was many years since, that Mr. Ward gave a beautiful illustration of the influence of food on plants. He found a perfect specimen of the common centaury half an inch high, with one or two pairs of most minute leaves and one flower, on the bare chalk at the border of a wood; on tracing it into the open parts of the wood, it became a glorious plant, four or five feet high, and covered with hundreds of flowers. He (Professor Redfern) wished to show that it was not only important to supply plants with food, but to do this so that they could easily appropriate it, otherwise the supply would be lost and wasted. He had brought with him a series of specimens of common rape, which would speak for themselves. The largest specimen measured five feet six inches high; they branched freely from the ground upwards at intervals of a few inches; their large leaves, thick and fleshy, measured fourteen inches by six inches, and their flowers once covered the plants with their brilliant yellow colour. The middle-sized specimens measured five feet two inches high, but for three feet from the ground they had no branch at all; their leaves were very small, and the plants were little more than a fibrous stem with a few flowers at the top.

The smallest specimens were only three feet high, having a few leaves not an inch long by three-sixteenths of an inch broad, and a few flowers at the top entirely useless for any purpose whatever. Other specimens of an essentially similar kind were grown on another spot of ground under circumstances essentially similar. Of those specimens a large number only measured fifteen inches high; they were furnished with a few almost linear leaflets and a few flowers at the top. Yet the larger specimens grown on this ground were five or six feet high, covered with large spreading branches, furnished with abundance of leaves, yielding a very large amount of good fodder compared with the amount of surface covered by them. With regard to the roots, those of all the poorer plants were straight, small, and but little branched; while those of the well-developed plants were thick, branched, and extended on one side only. For from four to six feet distant from the edge of the plot of rape, on each side the ground, had been trenched two spades deep for planting with trees and shrubs, and a quantity of bog earth with sand and manure had been mixed with it, the manure having been put at the bottom of the trench, and the mixed bog earth and sand half way down. The only well-developed plant grew near the edge of this trenched ground, and their one-sided root spread into it for two feet, exactly in the position occupied by the mixed bog earth and sand. There were only occasional smaller plants at this part, and the roots of every one of these were straight, short, and but little branched. They, in short, had not discovered that there was soft and spongy ground within so short a distance—ground in which their roots might have revelled in growth like those of their neighbour giants, if they had been equally fortunate in finding their way thither. None of the thick long roots on the trenched side of the plants penetrated deeply into the trenched ground. It was the loose and spongy condition of the soil that had attracted them, and not the manure, for not one root had attempted to penetrate to the depth of the manure; all had been content with the position of the mixed bog and earth and sand, thus affording an absolute demonstration of the necessity of attending to the mechanical condition of the soil as well as to its containing a sufficiency of the materials which plants needed for food. His plants of rape had abundant nourishment in their immediate vicinity, but they could not avail themselves of it, the soft spogioles of their roots being unable to penetrate the tough clay which a great amount of labour had failed to render porous enough for roots of any kind to enter to any considerable extent.

"Such was exactly the condition in which many persons were who had never applied their intelligence to the selection of their food or to the methods of taking it. There were few social problems more important than how to acquaint the wife of the labourer and artisan, or even the wives and servants of the middle classes, how to spend a fair share of their income upon food to the greatest advantage, and how to prepare it without destroying its nutritive properties. A savoury dish of meat was often prepared by mincing or cutting the meat into small and more or less cubical blocks. It was then stewed, or more frequently boiled; the outer surface of each little block had its albumen firmly coagulated, and the whole was converted into about as indigestible a mass as could well be imagined, the high priced and highly nutritious meat having been destroyed for the purposes of nutrition, and the action of the digestive organs probably injured for some time to come. Or good and valuable flesh meat was subjected to the process of salting, which, first of all abstracted the juices of meat, and then hardened the fibres, so as to destroy or greatly deteriorate its digestibility. No doubt it was convenient to have a hardened dry mass of meat incapable of much change for months, and ready to be used for the purpose of filling the stomach and effectually satisfying the appetite; but these were not the purposes for which food was intended to be used. It ought to be capable of

supplying the waste of the body, and of being easily converted into heat and motion. If it failed in these particulars, it would also fail in nourishing the brain, and aiding in the evolution of intelligence, and thus intellectual and bodily power was lost to the community, and deterioration of race was promoted. His colleague Dr. Gordon said that he recollected running races, putting stones, wrestling, and other athletic exercises being the favourite amusements of the sons and servants of the farmers in the county Down. Now nothing of the sort was heard of. These young men found a short day's work almost too much for them, and at the end of it they were to be seen lying about indulging in idle conversation. Coincidentally with this, they imagined themselves the equals of their masters and mistresses, and that the healthful oatmeal porridge and buttermilk twice daily, with beans and bacon for dinner, was too strong and coarse; they insisted on a more delicate fare, and demanded a supply of tea and white bread. They were unconscious that persons in their position but a few years ago possessed amazing vigour, and performed twice the amount of labour with greater ease, and when the day's work was over actually revelled in the display of surplus strength, which nothing but their better and more rational diet could have yielded them."

#### REMARKS BY THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND

ON

THE REPORT OF THE VISITORS APPOINTED BY THE  
GENERAL MEDICAL COUNCIL TO VISIT THEIR  
EXAMINATIONS,

*Held January 13th, 1874, and following days.*

THIS Council, having carefully studied the Report submitted for their consideration and remarks, whilst they observe, with pleasure, that the visitors consider that the final examination "combines, in a very appropriate and advantageous manner, a written, an oral, a clinical, and a practical examination," cannot but regret that the visitors, in the exercise of their discretion, considered it desirable and necessary to dwell so minutely and at such length on certain defects in the examination which they knew and acknowledged that the Council of this College had already taken active measures to remove.

With reference to the statement found in the commencement of the Report, p. 128, "We found, however, to our regret, that an important part of the examination, that, namely, in dissection, had taken place on the previous day," this Council would wish to remark that, in order to carry out the improvements in the conduct of the examinations at present in process of being adopted at the College, they found it necessary to require the dissections to commence on a day earlier than that which they had some time before informed the General Medical Council would be the day for commencing the examinations, and through inadvertence it was omitted to notify the General Medical Council of the fact, which, however, would have been done had any intimation been previously conveyed to them of the intention to have visitors present at the examinations in question.

With respect to the defects in the system of marking, to which allusion is made in the visitors' report, these had been recognised by this Council at a time considerably anterior to the date of the last visitations of the examinations of this College, and a recommendation adopted for its modification, whereby will be rendered impossible the improbable contingency of one examiner swamping the votes of his colleagues.

With regard to the suggestions made by the visitors, some of them, as endorsing their own views, this Council were glad to get, and either have adopted or are willing to adopt; amongst these may be mentioned those in reference to chemistry, forensic medicine, and histology. Always jealously alive to the necessity of modifying their examinations in accordance with the progress of medical science, this Council

have from time to time made such alterations as they deemed requisite; and some time ago appointed a committee to report, what changes and improvements were required in the form and style of their examinations. After most mature deliberation, extending over many months, a report was submitted to, and adopted by, this Council (a copy of which is herewith forwarded), which embodies, without exception, every suggestion in their opinion of any value contained in the report of the visitors of their examinations.

In this report it has been arranged to extend considerably the time for the writing of papers, and to include in that part of the examination questions on histology, which cannot satisfactorily be dealt with, as suggested by the visitors, at the oral examination; and whilst this Council are of opinion that botany should not enter into the subjects of examination for a surgical licence, they recognised its importance by retaining it in their curriculum. Provision also has been made for testing candidates in chemistry and medical jurisprudence the latter subject having been deferred to the second part of the examination, where, in their opinion, owing to its comprehensive nature, it should be placed.

In the reports both on the junior and senior class examinations this Council observe that the visitors take exception to the "short time that is allowed both to the written and oral parts of the examination." In their new scheme it is enacted that, for the first and second examinations, "four hours shall be allowed" for the written examination, and that for the *third* "one hour's examination at least" shall be given. This Council regret that this modification was not even alluded to by the visitors.

Other of the recommendations of the visitors this Council cannot adopt. Amongst these is their suggestion that, in the examination on operative surgery only one student should operate at a time. This, considering the very large number of candidates that at times present themselves, this Council consider would be impracticable, and they cannot see that any serious inconvenience to either the candidate or examiners can arise from there being more than one candidate operating on the same subject. In commenting upon this portion of their examinations, the visitors also call attention to the advisability of the examiners "submitting their questions to each other, or to the chairman, prior to the examination," absolutely quoting a by-law of this College to this effect, and seemingly implying that the by-law in question is ignored by the examiners. Now anyone conversant with examinations on operative surgery conducted on a large scale should be aware that such examinations could not be carried out at all were not such conferences held—held not so much for the purpose of securing "variety in the operations" as to ensure the practicability of thus examining a large class of candidates with but a limited supply of subjects. As a matter of fact, such conferences are always held, and however they escaped the visitors' notice, were held at the examination in question.

The visitors also seem to imply that the testing in operations is insufficient, drawing attention to the *apparent* similarity in the operations the candidates were called upon to perform. This Council reply that in their opinion it is unimportant the nature of the capital operation which the candidate may be called upon to perform so long as he is not informed of it beforehand; the great object in view being to ensure that all the candidates shall previously take out a course of operative surgery. The visitors also dwell upon the shortness of the time devoted to this portion of the examination. Upon this subject this Council would remark that, if four hospital surgeons of large operative experience are not competent to decide upon the merits of *five* candidates so far as operative surgery is concerned in the time admitted by the visitors to have been devoted to their examination (thirty-five minutes, a candidate being told off to each examiner), then, indeed, must they admit that their examiners are unequal to the task allotted them.

In connection with this subject this Council cannot avoid remarking, with regret, that the members of the General Medical Council failed to support the resolution brought forward by the representative of this College at the recent meeting of the General Medical Council (Minutes, p. 77), viz.:—"That, in the opinion of this Council, all examinations on anatomy should, so far as practicable, include the performance by each candidate of actual dissections; and that all those on surgery should include the performance by each candidate of two or more operations on the dead subject." This resolution, embodying as it does the collective opinions

of this Council, composed for the most part of hospital surgeons, all of them for several years engaged in the practice and teaching of surgery, should have commanded the support of the General Medical Council.

A comment similar to that made with reference to the examinations on Operative Surgery has been hazarded by the visitors respecting the clinical examination, viz.:—"The examination in clinical surgery was strictly limited to the ætiology and diagnosis of the cases exhibited. No questions were asked as to the various methods of treatment that might be adopted, nor as to the result that might be anticipated, though all the cases seemed to us to afford a fair opening for such inquiries." On this the Council of the Royal College of Surgeons in Ireland have to remark that the clinical examination requires much delicacy and tact. The patients on whom they are conducted are, for the most part, under the treatment of other practitioners, and have heard the clinical remarks made by them on the nature and treatment of their ailments. They must now listen to the observations of the candidates and examiners, and it can be readily understood how a conflict of such opinions might lead to an hospital being closed altogether against clinical examinations. This Council are, therefore, distinctly of opinion that the object of clinical examination should be diagnosis, pure and simple, and that treatment, which can only be elicited by question and answer, should be relegated to the oral examination.

With the opinion expressed by the visitors, "that the quarter-hour system of examination at successive tables is not well adapted for testing adequately the requirements of candidates," this Council must join issue, as, after long experience, they are convinced that examiners who cannot in this way determine, in conjunction with a written, clinical, and practical examination, whether a candidate possesses the requisite amount of knowledge, are incompetent to discharge the duties which they have undertaken. With reference to this portion of the examination, a remarkable misstatement is to be found in the Report, p. 131—"We are of opinion that two written questions on anatomy and one on physiology do not afford a sufficiently searching test of a candidate's knowledge of these important subjects, even when supplemented by an oral examination of *thirty minutes by two examiners*." The fact being that the oral examination is conducted on these subjects by *three* examiners, two on anatomy, for fifteen minutes each, and one on physiology, for fifteen minutes, in all forty-five, instead of thirty minutes. What renders this misstatement remarkable is, that the visitors state the facts correctly in another part of their Report (p. 129).

The doubt expressed in these words, to be found in the last paragraph of the first Report (p. 133), "The examinations, if the dissection be fairly carried out," this Council would remark is unworthy of the visitors, and by no means to be excused when contrasted with the following statement made by the same visitors in an earlier part of their Report (p. 128): "We were informed that every student had been required to dissect for about half an hour, and on examining the subject we found that the vessels, nerves, and muscles of the axillary space on both sides, as well as those of the right side of the neck, *had been fairly* made out, and that the skin and superficial fascia of the inguinal region and upper part of both thighs had been reflected;" an amount of dissection, in the opinion of this Council, quite sufficient to test the knowledge, in practical anatomy, of the very small number of candidates examined on that occasion—eight, of whom seven were rejected. Did any suspicion lurk in the minds of the visitors that the dissections had not been *fairly* carried out? Had they any grounds for entertaining such a supposition, they should have boldly given expression to it in unequivocal terms. If, on the contrary, they entertained no such suspicion, then never should this sentence have found place in their Report.

With reference to the following remarks of the visitors, in the first paragraph, p. 142:—"The examination in the practice of medicine by two examiners was on erysipelas, permanent patency of the aortic valves, and hypertrophy of the heart, pleurisy, and pneumonia. A few questions were asked on treatment, but it was not possible, within the time allowed to each examiner, to give a full or satisfactory examination on any of the diseases." From the language in which the visitors have couched this sentence, it might be inferred that every candidate had been examined within the fifteen minutes allotted to the *visd voce* examination on practice of medicine, upon all of these diseases—a style of examination

which would, indeed, be of a superficial character. Such, however, was not the fact, some of the candidates having been examined on one, some on another, of the diseases enumerated.

With reference to the selection of the visitors employed to report on the system of examination pursued at their College, this Council would remark that, to report upon the examinations conducted for surgical licences, it is their opinion that operating surgeons and practical anatomists are the proper persons to whom the discharge of such duties should be confided. Visitors, no matter how otherwise eminent they may be, unless they also fulfil these conditions, cannot be supposed to be familiar with the requirements to be expected from candidates for surgical licences, nor can their reports be expected to have much weight attached to them by persons whose life-long work has been the discharge of surgical duties. And this Council cannot avoid remarking how much it is to be deplored that, in making their selections of visitors outside the members of the Council, the executive committee did not act in accordance with the view expressed in the fourth paragraph of the Report of the committee on visitation of examinations (p. 62, vol. x., Minutes of Medical Council), viz.:—"That each examination reported on shall be visited by a due proportion of members of the branch councils *other than the one in that division of the kingdom where the examination is conducted*,"—all the outside visitors in the past year having been selected from but one of the divisions of the kingdom.

In concluding their remarks, this Council would wish to observe that it is much to be regretted that the course pursued by the majority of the members of the General Medical Council, when the consideration of the report of the visitors of the examinations at the Royal College of Surgeons in Ireland came under discussion, was so completely at variance with that pursued in the case of the other bodies reported upon. This Council feel that such a line of conduct was as unjust as it was uncalled for; especially uncalled for when the members had been informed by their visitors that the Council of this College were busily engaged in remodelling the mode of conducting their examinations, and in remedying any defects which might be supposed to exist in them. They have failed to find in the Report, especially when they compare it with the reports of the visitation of the other bodies submitted to the consideration of the General Medical Council, any justification for a resolution, the tone of which is so calculated to engender feelings of irritation, and to disturb the harmony which should exist between the General Medical Council and the medical authorities. Having planned long before the visitation every modification worthy of consideration suggested by the visitors, they are putting these modifications into actual and immediate operation, even without receiving a guarantee (to which, however, in justice to their corporation they feel themselves to be entitled) that a similar examination will be required from any other of the medical authorities claiming the registration of their licence. And this, too, notwithstanding their knowledge of the fact, of which they have had repeated painful experience (a fact of which the members of the General Medical Council also, after their late meeting, can no longer plead ignorance), that candidates rejected by one of the licensing bodies can secure, without loss of time or further preparation, through another portal, insertion of their names on the General Medical Register.

## Literature.

### DISEASES OF THE SKIN. (a)

THE greater part of the present volume has been written by Dr. Kaposi, Professor Hebra's assistant, who has also aided Mr. Warren Tay, the able translator, in revising the work. The extensive experience of Mr. Tay in the Blackfriars Hospital has moreover enabled him to make the treatise most useful for English readers. Three of the ten classes of cutaneous maladies are discussed in the volume—namely, hypertrophies, atrophies, and benign growths, so that the chapters on lupus, leprosy, and carcinoma are all that are wanted to complete the treatise. Under the head of keratoses are included corns, warts, condylomata,

(a) "Diseases of the Skin," Prof. Hebra. Vol. III. The New Sydenham Society. 1874.

ichthyosis, and some minor affections, and the following description of the anatomical structure of the second variety is as follows: "Whatever may be the size and form of a wart or of a pointed condyloma, it always consists of a connective tissue framework, which determines the form of the excrescence, in whose interior a vascular loop is found, and whose exterior is covered with a more or less thick epidermic layer.

The earlier observers were of opinion that such an outgrowth of warty and condylomatous formations could only occur from an existing papillary layer, that is, from the papillæ themselves. But the circumstance that similar formations appear on such parts of the skin where no papillæ exist, and also on mucous membranes as well as on other tissues, shows that a pre-existing papilla is not necessary to their production.

For warts which project, excision with curved scissors is advised, and for those which are more sessile, fluid caustics, such as sulphuric acid. In such latter case the surrounding skin can be protected by pressing over the wart a small lump, of softened wax, and then scratching away the portion over the wart, a receptacle is thus easily made for the caustic fluid, and the surrounding skin is protected.

The chapter upon ichthyosis, as is usual in all Hebra's writings, is most copious in respect of history, classification, and anatomy, and most scanty as regards treatment. The case of the famous Irishman, Edward Lambert, who, as well as several of his family, were exhibited all over Europe, is detailed in support of the theory that the disease is hereditary. Further, our author says: "It is easily explained why ichthyosis should be hereditary, especially in families where it has been handed down from parents to children in unbroken succession. We need only recall to mind that the children of the Ethiopians, of the Indians, and of the other races of men resemble their respective parents in so far that they as a rule have a similar colour of the skin, if not immediately after birth, at any rate, at an early period of life."

That ichthyosis may develop without any hereditary characters, and in middle age, was, however, proven by a case published by Dr. Mapother in the *Dublin Medical Journal* for June, 1873.

The chapters on diseases of the hair will amply repay perusal, and now-a-days our profession should possess and utilise information on this subject, for owing to the labours of the hair-dresser and hair-dyer, this class of affection must rapidly and largely increase.

In the chapters on keloid and angiomas, Dr. Kaposi gives a very full and accurate account of their anatomical characters. With regard to the latter, all surgeons are familiar with such tumours, composed of erectile and dilated blood-vessels, but that a like morbid condition may come upon lymphatic vessels appears from the following case, which we very briefly summarise from our author, who regards it as unique:—

Patient unmarried female, æt. 32, quite healthy otherwise. Embedded in the cutis all over the body there were hundreds of brownish tumours, the size of lentils, projecting superficially, and to an equal degree into the areolar tissue under the skin. They had existed from childhood, but had latterly increased. One tumour was excised, and upon microscopic examination was found to consist of intercommunicating lymphatics, the blood-vessels being of normal size.

In conclusion, we may assure our readers that the third volume contains descriptions of cutaneous maladies quite as erudite and as accurate as those in the two preceding, although they do not possess such practical import, owing to the infrequency of the affections.

#### LECTURES ON AURAL CATARRH. (a)

DR. PETER ALLEN had nearly completed a second edition of his meritorious "Lectures on Aural Catarrh"

(a) "Lectures on Aural Catarrh: or, the Commonest Forms of Deafness and their Cure." By Peter Allen, M.D., &c. Second edition. Churchill, 1874

when he fell a victim to an attack of enteric fever, which he took immediately on his return home from his vacation holiday. His loss will be long and severely felt, since his place in society and in that special department of medicine in which he practised and had attained to a high reputation will not be so easily filled. His kindness of heart and his genial friendship lives in the memory of those who had the pleasure of his acquaintance.

These Lectures, already favourably known to the profession, contain the essence of the work of the thinker, the student, and the successful practitioner, and we doubt not will be long consulted by the profession. The illustrations of the anatomy of the internal ear are most carefully executed, and upwards of one hundred pages of new matter have been added. The information throughout is quite up to the mark, and is of an eminently practical and useful character.

#### THOMSON'S CONSPECTUS. (a)

A NEW edition of "Thomson's Conspectus" has just appeared. We welcome our old pocket companion of the *Pharmacopœia*, carefully revised, as it apparently is, and brought up to the present time by the addition of a supplement and an appendix, with notices of new medicines and preparations contained in the additions of the British *Pharmacopœia* (May, 1874), and useful remedies employed on the Continent and in America.

Although the editor, Dr. Birkett, dedicates his little book to the junior members of the profession, doubtless the senior members will find it equally serviceable, since it is perfectly certain that "the pictures drawn in our minds are laid in fading colours, and, if not sometimes refreshed, vanish and disappear." Indeed, as we grow older, our multifarious and extended pursuits, together with the anxieties of life, tend to obliterate the botanical, chemical, and therapeutical properties of the larger portion of the substances contained in the *Pharmacopœia*, and hence the necessity for this handy little book of reference, which can be conveniently carried about in the pocket.

#### ON THE ADMINISTRATION OF PHOSPHORUS. (b)

DR. EDMUND KIRBY, to whom the general practitioner is very largely indebted for a ready method of dispensing, has published a valuable and timely little brochure, "On the Administration of Phosphorus." Although phosphorus has long been known as a powerful remedial agent, it has apparently not been employed to any extent in this country, and therefore we are inclined to think, with Dr. Kirby, its neglect has arisen from the absence of official formulæ rather than from a want of clinical experience of its value. This would seem to receive confirmation from the fact that Dr. Pereira, in his "Materia Medica," years ago wrote of phosphorus. "After its absorption it acts as a stimulant to the nervous, vascular, and secreting organs. It excites the mental faculties and the sexual feelings, raises the temperature of the skin, increases the frequency of the pulse, promotes the secretions, and operates as a powerful sudorific and diuretic. It is administered as a stimulant to the nervous centres in convulsive and old paralytic states," &c.

Notwithstanding what was written and known of phosphorus in this country and its employment in America and on the Continent, it was not until May of the present year, when an extravagantly costly supplement of the British *Pharmacopœia* made its appearance, that any attempt was made to furnish the profession with a stable formula for its administration. Dr. Kirby long before this undertook to supply the omission, and now gives, besides a simple pill, a number of useful combinations of phosphorus with iron,

(a) "Thomson's Conspectus, adapted to the British Pharmacopœia." Edited by E. Lloyd Birkett, M.D. Cantab. Longman, Green, and Co. (b) "On the Administration of Phosphorus." By E. A. Kirby, M.D., M.R.C.S., &c. Lewis, Gower Street, London.

quinine, nux vomica, &c., &c., that he and other practitioners have found useful in cases of exhausted nervous power, functional paralysis, nervous headache, neuralgia, hysteria, melancholia, as well as in furuncular inflammations, carbuncle, and certain skin affections. This concisely written pamphlet will do much towards restoring a valuable therapeutic agent to a proper position in the British Pharmacopœia.

## Correspondence.

### THE RELATIONS OF THE PROFESSION TOWARDS HOMŒOPATHY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having but lately returned to town, your comments on my address before the British Homœopathic Congress were not seen by me until to-day, and I would ask your kind permission to say a few words in my own defence.

You characterise as a "gross misrepresentation" my statement that a majority of the profession treat as "unworthy to be regarded as members of an honourable profession, as immoral individuals with whom it would be ignominy to associate," some of their colleagues for acting on their conviction that most diseases are best treated by medicines that act similarly to the morbid cause—in other words, homœopathically. You say: "The medical profession does not refuse to associate with homœopaths for any such reason; but, on the contrary, regards with the most perfect toleration the theory and practice of *similia similibus*." You further state that it is the infinitesimal dose that is "the reason for the exclusion of homœopaths by the profession."

Now, it is a very serious thing to be accused of "gross misrepresentation," and I do not suppose I shall appeal in vain to your sense of justice to allow me to lay before your readers some of the evidence on which I founded the statement you thus characterise. I could, I am sure, adduce a large amount of testimony from the medical periodicals in proof of my allegation; but, with all deference to you, I believe the resolutions of public bodies like colleges and societies express the sentiments of the medical profession better than "utterances of professional journals," for I have not been editor of a professional journal for thirty years without knowing that the editorial plural "we" often masks the singular "I."

On the 9th of May, 1851, the Royal College of Physicians of Edinburgh passed resolutions against homœopathy in which, after referring approvingly to it having, in 1842, "peremptorily declined to admit into its body a candidate for its Fellowship because he practised homœopathically," it goes on to say that "those of its Fellows who have become homœopaths, or any other medical practitioners who follow homœopathy, must necessarily be alien to the other Fellows and to the profession at large, inasmuch as no Fellow of the College, nor any other physician can, by any possibility, without derogating from his own honour and from the honour of the profession, meet practitioners of homœopathy in consultation, or co-operate with them in the other common duties of professional life."

On the 14th of August, 1851, the Provincial Medical and Surgical Association (now the British Medical Association) passed resolutions against homœopathy in which we find the following phrases: "That it is derogatory to the honour of members of this Association to hold any kind of intercourse with homœopathic practitioners." "That there are three classes of practitioners who ought not to be members of this Association, namely: 1st. Real homœopathic practitioners; 2nd. Those who practice homœopathy in combination with other systems of treatment; 3rd. Those who, under various pretences, meet in consultation or hold professional intercourse with those who practise homœopathy." "That the thanks of the Association are eminently due, and are hereby given to the Presidents and Fellows of the Royal College of Physicians and Surgeons of Edinburgh for their determined stand against homœopathic delusions and impostures." "That the thanks of the Association are also due, and are hereby given to the Universities of Edinburgh and St. Andrew's for their resolution to refuse diplomas to practitioners of homœopathy."

In 1851, Dr. R. D. Hale passed his examinations, and obtained his degree at St. Andrew's. The Faculty of that University, learning that Dr. Hale was a homœopathic practitioner, demanded back his diploma.

In 1851, Dr. J. S. Clarke took his degree at King's College, Aberdeen. Soon afterwards some one wrote to the *Lancet* that Dr. Clarke was a homœopathic practitioner. Dr. Type, the Professor of Medicine of the College, wrote to the *Lancet*: "I beg to inform you that, at the time of his examination, not the slightest suspicion was entertained of his being a homœopathic practitioner, otherwise the degree would not have been conferred on him."

In 1858, Mr. Harvey desired to obtain the degree of M.D. at Marischal College, Aberdeen. He passed the two first examinations satisfactorily; but a report of his homœopathic proclivities having reached the examiners, Dr. Macrobin, in the name of the Faculty, questioned him as to his having practised homœopathically. Mr. Harvey objected to reply to such an inquisitorial question, and Dr. Macrobin refused to admit him to the final trial until he should be satisfied that the candidate had never practised homœopathically. In a correspondence that ensued, Dr. Macrobin required from Mr. Harvey "a distinct declaration that, as a man of honour, you have not practised and do not entertain any intention of practising the profession on other principles than those taught and sanctioned in this and other legally recognised schools of medicine; that homœopathy or any other species of irregular unauthorised practice is what you entirely repudiate."

On the 28th of January, 1859, the Liverpool Medical Institution, by a large majority, altered one of their rules to this effect: "But no one practising homœopathy shall be eligible as a member of the institution or as a subscriber to the library, and any member or subscriber who may become a practitioner of homœopathy shall cease to belong to this institution."

On the 10th of August, 1861, the Royal College of Surgeons of Ireland adopted the following ordinance: "No Fellow or Licentiate of this College shall pretend or profess to cure diseases by the deception called homœopathy." "It is also hereby ordained that no Fellow or Licentiate of this College shall consult with, meet, advise, direct, or assist any person engaged in such deception or practices, or in any system of practice considered derogatory by the physicians or surgeons."

I need scarcely say that all these resolutions, as they appeared in turn, were vehemently applauded by every organ of orthodox medical opinion, and that not one feeble protest appeared in the professional journals against even the most extravagant of them.

I might give a long list of societies, medical, medico-ethical, and registration, which have passed laws excluding homœopaths from membership, and even imposing the penalty of expulsion on those of their own members who should meet homœopathic practitioners professionally; but the above will suffice.

The same system has been carried on by the orthodox majority of the profession on the Continent and in America. So late as 1871 the Massachusetts Medical Society attempted to expel its homœopathic members by resolving that any one who "adopts as his principle in the treatment of disease any exclusive theory or dogma shall be deemed to have violated the by-laws of the society by conduct unbecoming and unworthy an honourable physician and member of this society."

I may conclude this list of my proofs with one from the other side of the Channel. On the 4th of January, 1856, under the presidency of Professor Cruveilhier, the Anatomical Society of Paris expelled by an unanimous vote "Drs. J. P. Pessier, Gabalda, Fredault, and Jousset, as authors of homœopathic publications, and M. W—, on account of an infamous and felonious act already punished by the law."

If, Sir, I have been guilty of "gross misrepresentation" in alleging that the majority of the profession have treated us as unworthy to be regarded as members of an honourable profession, as immoral individuals with whom it would be ignominy to associate, on account of our endeavour to act up to our conviction that diseases are best treated homœopathically, you will surely allow that I had some grounds for the statement; and if it be the case, as you assert, that "the medical profession regards with the most perfect toleration the theory and practice of *similia similibus*," then you will admit that the language of the resolutions, &c., I have quoted above must have been used *à la Talleyrand*, to conceal thought, for to an ordinary understanding, and in its literal sense, it seems to have quite an opposite meaning. However, we are glad to

have your high authority that the medical profession regards the theory and practice of homœopathy with the most perfect toleration, only we cannot help feeling as puzzled by those demonstrations of toleration as was the poor fellow in the poem who exclaimed

"Perhaps you were right to dissemble your love;  
But why did you kick me down stairs?"

Your obedient servant,

R. E. DUDGEON, M.D.,  
President of the British Homœopathic Congress of 1874.

53 Montagu Square, London,  
29th August, 1874.

[Our correspondent very conclusively proves that which required no proof—*i.e.*, that the medical profession adopts a relation towards homœopaths which implies that they are unworthy to be regarded as members of an honourable profession. We have been perfectly well aware of the existence of the *pronunciamentos* which he quotes, and yet we reiterate our statement that "the medical profession regards with the most perfect toleration the theory and practice of *similia similibus*," but that it is nevertheless a gross misrepresentation to state that homœopaths are ostracised for holding this dogma or practising upon its principle. The medical profession recognises the perfect right of any practitioner to hold any view, however ridiculous and unscientific, and to apply such theory in his practice so long as he does so with honest confidence in its efficiency. The medical profession, therefore, does not put hydropaths in the same category as homœopaths, although the great majority of its members believe the universal practice of water-doctoring to be a delusion and a snare. Homœopaths are not admitted to association with the profession, and have been made the subject of the denunciatory resolutions quoted by our correspondent because it is impossible for intelligent minds to place any charitable construction upon the practice of infinitesimalism, or, in fact, to believe that it is anything but a fraud. Homœopaths may, if they like, be visionaries; but they must establish their claim to be considered to act with honest intention before they can be met as fellows by scientific medical men. It is a matter of some importance to the profession that its members should not, without contradiction, be accused of persecuting any person because he does not agree with them in their own views; and it is necessary, in justice to medical men, to assure the public that homœopaths are not entitled to any sympathy as martyrs at the shrine of science, but are excluded from the pale of the profession because they are guilty of what medical men consider to be a public fraud.—ED. M. P. & C.]

### SUCCESSFUL CANDIDATES FOR THE INDIAN MEDICAL SERVICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

THE Military Secretary, India Office, presents his compliments to the Editor of the MEDICAL PRESS, and begs to enclose for publication a list of the candidates for Her Majesty's Indian Medical Service who were successful at the competitive examination held at Burlington House on the 10th August, 1874. Twenty-eight candidates competed for fourteen appointments. All were reported qualified.

## Gleanings.

### Infant Diet.

By A. JACOBI, M.D., Clinical Professor of Diseases of Children, College of Physicians and Surgeons, New York.

*Of the Nursing Infant.*—"But a much more frequent occurrence (than the increase in the normal percentage of salts) is too large a percentage of casein in mothers' milk. Casein will be curdled in hard masses, or will pass into the intestines in the same condition, and be evacuated almost unchanged, or covered, perhaps, with a bile, a little viscid mucus, sometimes even with a streak of blood. The indications are either preventive or curative. The increase of casein is frequently accompanied by a diminution of sugar, and the absolute neutrality may be replaced by a faint acidity; and the effect is constipation. I remove it (the constipation) in many instances, by simply adding a moderate amount of sugar to the normal food. One or two scruples of loaf sugar are dissolved in one or two teaspoonfuls or more of tepid water, and given to the baby just before nursing. The next indication is to prevent the too sudden effect of the gastric juice upon the surplus casein, and keep it from coagulating in hard masses. Instead of the sugar-water mentioned above, I give the baby each time before it is put to the breast a tablespoonful or more, according to age, of strained and well-sweetened oatmeal, for reasons, and prepared in a manner I shall designate hereafter. For this plan, also, which has been serviceable in many cases where the former simple one would not suffice. I claim good theoretical reasons, and the result of various, and, I believe, unbiased observation of a long number of years. The third indication is curative, and refers to the correction of the excess of acid of any origin that may exist in the digestive organs. The main concomitant symptoms of acidity are either constipation or diarrhoea, the principal alkalis in question, preparations of potassa, soda, lime, or magnesia. Wherever neutralisation is required in a case of constipation, we should resort to magnesia, soda, or potassa; whenever we have to deal with a diarrhoea, carbonate of magnesia would be indicated. Whenever no decided indication was to be followed, we might select either of soda or potassa, the bicarbonate or the carbonate: the latter, however, when given in large doses, is too ponderous and less digestible than the former."

"Artificial feeding cannot be successful without milk. Where the choice is given, therefore, cow's milk ought to be preferred. There is in cow's milk less sugar, less of free alkali, less butter, but more and more coagulable casein. Practically, when a relative deficiency of sugar in cow's milk is to be supplied, loaf sugar always answers the purpose. It is advisable to add an alkaline salt (the carbonate or bicarbonate of potassa or soda) to the cow's milk, and best at once when the milk is put aside for the infant's use. Thus I add one or two grains of either of the salts to every meal of the new-born, besides a small quantity of the common salt—chloride of sodium—and a larger dose in proportion to age. Cow's milk ought to be cooked at once, in order to keep it as long as possible from turning sour, and ought to be preserved in a cool place, if not in an ice-box. Next in order is the question how to prevent the great coagulability of the casein of cow's milk; I add instead of water a substance which, by its physical consistency and coersion, is apt to hold milk in suspension. Thus I mix, say, quite thin and transparent mucilage with (boiled and skimmed) milk, and add the desirable quantity of sugar and salt, or soda. Looking for a substance which, while fulfilling that object, is absolutely indifferent from a chemical and physiological point of view, it is gum arabic. An indifferent substance of this sort may be all that is desired for very young infants; the selection of articles of food, which are, at the same time, of a mucilaginous consistency, and nutrient, is perhaps not so difficult as it appears to be. Barley and oatmeal are the two substances I most employ. A teaspoonful of either is boiled in from three to six ounces of water with some salt [a pinch] for twelve to fifteen minutes; the decoction is to be quite thin for very young infants, thicker for later months, and then strained through a linen cloth. Infants of four to six months are to have equal parts of this decoction, which ought to be made fresh for every meal; and (boiled and skimmed) cow's milk and sugar is to be added. The desire of parents to procure the milk of one special cow for their infants I believe to be based upon a mistake. I have always advised the plan of giving the average milk of a farm, and have never been sorry for the results, in all parts of the city."

## Medical News.

**King's College.**—The governors of King's College are enlarging the accommodation of the present building. A new wing, one storey high, in a similar style of architecture with Somerset House, and fronting the Thames Embankment, is being rapidly pushed forward. The dissecting-room and laboratory are being considerably enlarged, and new consulting-rooms and offices erected. The students' rooms are undergoing alteration and improvement, and a new and commodious drawing school is in course of construction. It is expected that the whole will be completed in time for the winter session.

**Bequests to Medical Charities.**—Mr. Walter Tucker, of Weston-super-Mare, has bequeathed £500 each to the Bath Mineral Water Hospital, the Bath Royal United Hospital, the Bath Eastern Dispensary, the Southern Dispensary, Widcomb, the Bath Eye and Ear Infirmary, the Weston-super-Mare Hospital and Dispensary, and the Royal Hospital for Incurables, Putney.

### NOTICES TO CORRESPONDENTS.

**✎** CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

#### INDIAN SPECIAL CORRESPONDENCE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—What a pity your Indian "Special," for whose communications I look forward as eagerly as for my weekly *Punch*, did not give us his authority for the remarkable statement that Oliver Cromwell "was buried by soldiers puffing (tobacco) vigorously in derision." He ought to lose no time in communicating it to Mr. Carlyle, who would, no doubt, gratefully immortalise him in the next edition of his "Life" of the great Protector.

Yours obediently,

SOME SIDES.

**PRIZE ESSAYS.**—We are asked to state by the editor of the *Greenhithe Monthly Magazine* that the society of which this magazine is the organ propose offering an annual prize of Five Guineas for the best essay on some subject of special interest to the inhabitants of rural and suburban districts. The subject for the first prize will be, "On the Comparative Healthiness of Country and Town Life, and the best means of applying Sanitary Science so as to ensure the Highest Development of Health, and the Prevention of Disease." The successful essay to become the property of, and be published in the *Greenhithe Magazine*. The terms and particulars of the prize can be obtained by forwarding a stamped directed envelope, addressed to the Editor, Greenhithe, Kent.

**A MEDICAL ALLIANCE.**—Readers will probably have innumerable cases of vexatious prosecutions of members of the profession in their minds, notably that of Mr. Pope, of Brixton, upon which we commented in our last. We now observe that "A Medical Alliance" has been started for the purpose of defending members of the profession who from time to time are made victims of extortion and false accusations. Before, however, giving such an Alliance our support, we shall want to know that the remedy is not worse than the disease. Who is the hon. secretary and who the committee, of this quickly constituted "Medical Alliance"? We have no doubt it is all fair, and above board, but we want to be assured of the fact; no gentleman attaching his name to so laudable an undertaking need be ashamed of it.

**MILITARY SERVICE OF MEDICAL OFFICERS.**—Though, under the provisions of the Royal Warrant of 1873, military service is no longer necessary, as a qualification for promotion to the rank of Surgeon-Major, it has been intimated under instructions from the Secretary of State that Government will take into consideration the amount of military service a medical officer has performed in making selection for the administrative rank.

#### BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

*Incrustations sur la Lèvre Vocale.* Par le Docteur Mandl. Paris and London: Baillière.

*Nomenclature of Diseases, prepared for the Use of Medical Officers of the United States' Marine Hospital Service.* By J. M. Woodworth, M.D., Washington.

*On the Past Progress and the Present Aspects of Medicine.* By Alex. Harvey, M.D. Aberdeen.

*Archives of Ophthalmology and Otology.* Vols. III. and IV. New York: Wood and Co.

#### VACANCIES.

Dorset County Hospital. House Surgeon and Secretary. Salary, with apartments and board. Testimonials, &c., under cover to the Chairman at the Hospital.

Bristol General Hospital. Physician's Assistant. Salary, £50, with board and lodging. Applicants must address the Secretary.

Convalescent Hospital, Wimbledon. Resident Medical Officer. Salary, £75, with board, &c. Further particulars of the Secretary of St. George's Hospital.

Northampton Infirmary. Dispenser. Salary, £100 per annum. Further particulars of the Secretary.

York Lunatic Asylum. Resident Medical Superintendent. Salary, £300 per annum, with residence, vegetables, coals, gas, &c. Applications to the Committee, under cover to the Secretary, Bootham, York.

Newcastle-on-Tyne Infirmary. Senior House Surgeon. Salary, £100 per annum, with board and residence. Particulars of Dr. Page at the Infirmary.

Southport Convalescent Hospital. Resident Medical Officer. Commencing salary at £80, with board and attendance. Applications to the Chairman of the Hospital.

Gloucester County Prison. Surgeon. Salary, £175 per annum. Full particulars on application to the Governor.

Sunderland Infirmary. Junior House Surgeon. Salary commencing at £60 per annum, with board and residence. Address the Secretary to the Medical Board.

Narberth Union. Medical Officer for District No. 2 of the Union. Emolument, £35 per annum, with fees extra. Address the Clerk to the Board.

Three Counties Pauper Lunatic Asylum. Resident Medical Superintendent. Salary, £800, with furnished house, coals, &c. Applications to the Clerk to the Committee, St. Neots, Hunts.

#### APPOINTMENTS.

BARR, J., M.B., L.R.C.S. Ed., Junior House Surgeon to the Northern Hospital, Liverpool.

BIRTHWISTLE, W., M.R.C.S.E., Medical Officer for the Skipton District and the Workhouse of the Skipton Union, Yorkshire.

CHARTRIS, WILLIAM, L.R.C.S.I., L.K. & Q.C.P.I., Medical Officer to the Strangford Dispensary, Downpatrick Union.

DAVIES, J., M.D., M.R.C.S.E., Medical Officer of Health for the Ebbw-valle Urban Sanitary District.

FOTHERGILL, J. MILNER, M.D., M.R.C.P., Physician to the West London Hospital, vice Prof. D. Ferrier, M.D., appointed Assistant Physician to King's College Hospital.

FOX, C., M.R.C.S.E., Medical Officer and Public Vaccinator for the Topeham District of St. Thomas Union, Exeter.

GIVEN, M., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer and Public Vaccinator for the Blessington and Ballymore-Eustace Dispensary District of the Naas Union, co. Kildare.

GRIFFITH, R. G., M.R.C.S.E., Medical Officer to the East Indian Railway at Benares.

HARRIS, J. A., M.B., M.R.C.S.E., Senior House Surgeon to the Northern Hospital, Liverpool.

HARRIS, W., L.R.C.P. Ed., M.R.C.S.E., Resident Medical Superintendent of the Norwich Lunatic Asylum.

HODGSON, W., M.R.C.S.E., Medical Officer and Public Vaccinator for the Aspatia District of the Wigton Union, Cumberland.

MACCARTHY, E., M.D., M.R.C.S.E., Medical Officer for No. 3 District of the Dursley Union, Gloucestershire.

MACPHERSON, C. M.B., L.R.C.S. Ed., Medical Officer for the Parish of Stromness, Orkney.

PHILLIPS, E. E., L.R.C.P. Ed., M.R.C.S.E., Medical Officer for the Prittlewell District of the Rochford Union, Essex.

POWELL, J., M.R.C.S.E., a Junior House Surgeon to the Royal Free Hospital, London.

PRISTLEY, C. E., L.R.C.P. Ed., M.R.C.S.E., Resident Medical Officer to the West Norfolk and Lynn Hospital.

REID, A. W., M.B., C.M., L.R.C.S. Ed., Physician-Superintendent of the City of Glasgow Fever Hospital.

RICE, G., M.B., House Physician to the Royal Infirmary, Manchester.

ROBERTSON, J. A., M.B., Parochial Medical Officer for Wemyss, Fifeshire.

ROBERTSON, J. D., M.D., Medical Officer of Health for the Penrith Rural Sanitary District.

## Marriages.

AKERMAN—WARLAND.—On the 29th ult., at St. Mary's Church, Paddington, William Akerman, L.K.Q.C.P.I., M.R.C.S.E., of Golborne Road, Upper Westbourne Park, to Annie, only surviving daughter of the late Capt. Warland, of Poole, Dorset.

ALLWOOD—HARDERN.—On the 2nd inst., at St. James's Church Sutton, near Macclesfield, J. Philip Allwood, M.R.C.S., L.R.C.P., of Macclesfield, to Elizabeth Thorneycroft, only daughter of Wm. Thorneycroft Hardern, M.R.C.S., L.A.C., &c., of Sutton.

FERRIER—WATERLOW.—On the 3rd inst., at St. John's Church, Redhill, David Ferrier, M.D., Professor of Forensic Medicine, King's College, London, to Constance Eliza, third daughter of Mrs. Albert C. Waterlow, Fairlawn, Redhill, Surrey.

VEREKER-BINDON—DOWNIE.—On the 2nd inst., at St. Peter's Episcopal Church, Edinburgh, William John Vereker-Bindon, L.R.C.P.E., L.R.C.S.E., to Mina, youngest daughter of the late Thomas Walters Downie, Esq., Trinitium, Stirling.

SPARKS—PANTON.—On the 2nd inst., at Holy Trinity Church, Dorchester, Edward Isaac Sparks, M.A., M.B. Oxon., of London, to Sarah Emily, second daughter of the late George Panton, Esq., of Dorchester.

## Deaths.

BALLARD.—On the 1st September, Thomas Ballard, M.D., of Southwick Place, aged 56.

DOWLING.—On the 19th August, James Harnett Dowling, M.D., of Cerne Abbas, aged 60.

POTTER.—On the 29th August, at Kilkenny, John Potter, M.D.

Established 1848.

PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S., &c. (KING'S COLLEGE), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

PRACTICES AND PARTNERSHIPS NOW OPEN for Negotiation (in addition to those advertised in Dr Langley's List, which is sent post free on application).

Z 16. OPENING for a gentleman with limited capital in the suburbs of a large town. An efficient introduction, by way of partnership, can be given by an aged practitioner, retiring from ill-health. Present receipts about £400 a year, but scope for almost unlimited increase.

Z 15. Within twenty miles of London, AN EASILY-WORKED PRACTICE, consisting wholly of an upper-class connection. The receipts are about £400 a year, but in the hands of an active gentleman £1,000 a year might be earned. Very little night work. House contains ten rooms, with beautiful garden, paddock, &c. Rent, £40.

Z 14. SUFFOLK. EXCELLENT UNOPPOSED PRACTICE FOR SALE. Receipts £450 a year, capable of immediate increase. Appointments, £60. House contains twelve rooms, and is pleasantly situated; rent low. Introduction as long as desired.

Y 950. In the Suburbs of London, an OLD-ESTABLISHED PRACTICE, yielding £1,000 a year. Patients good class. All appointments have been declined. Visits, 4s. and upwards; midwifery chiefly £2 2s. and upwards. One horse and carriage sufficient for the work. The house is well situated in a pleasant and healthy locality, contains eight rooms, and is held on beneficial lease at a rental of £80 a year. The whole Practice is easily worked, and the connection lies within a small area. The Incumbent is retiring from the profession.

Z. 13. GLOUCESTERSHIRE. PLEASANT COUNTRY PRACTICE, realising about £500 a year, FOR TRANSFER. Midwifery fees chiefly £2 2s. No opposition. Appointments bring in £60. The house is convenient, with stabling, coach-house, &c. A thoroughly efficient introduction can be given.

Z 12. In a pleasant and prosperous town in the Midland Counties, A WELL-ESTABLISHED PRACTICE, yielding between £600 and £700 a year. Patients good middle class. The house is the best in the town, contains sixteen rooms, with offices, stabling, and coach-house. Rent, £90. A smaller professional residence can be had if required, as the Incumbent desires to enter upon a partnership conditionally arranged elsewhere. Liberal terms would be conceded to a suitable purchaser.

Z 11. Near the sea-side. In a pleasant town, a WELL-ESTABLISHED PRACTICE FOR TRANSFER on easy terms. The present receipts average about £470 a year. Easily worked appointments produce about £300 a year. No assistant required. One pony sufficient for the work. Large and convenient house, with garden, stabling, and coach-house. Rent, £30. There are about sixty midwifery cases a year, the majority at £1 ls. Only one opponent. Premium, one year's purchase, part of which may be left on security to suit the convenience of purchaser. An effective introduction as long as desired.

DR. LANGLEY'S SEPTEMBER LIST of Selected Practices and Partnerships for negotiation is now ready. Post free on application.

NEWPORT UNION.

ACHILL DISPENSARY DISTRICT.

TO MEDICAL OFFICERS.

The COMMITTEE OF MANAGEMENT of the Achill Dispensary District will on TUESDAY, the 15th day of SEPTEMBER next, proceed to Elect two

MEDICAL OFFICERS for the above District, at a Salary of One Hundred Pounds a year each.

The District is divided—viz., the Achill District and the Ballycroy District.

The Achill District comprises the Electoral Divisions of Achill, Dooga, and Slievemore, and a portion of the Corraun Achill Division. The Ballycroy portion of the District comprises the Electoral Divisions of Ballycroy North, and Ballycroy South, and the Townlands of Dooaghbeg, Cushlicka, Cuilloughan, Owenduff, and Tonreege East and West.

The Medical Officer of the Achill portion of the District has heretofore held the appointment of Surgeon and Agent to the Admiralty, which is an office of considerable emolument, and there is also a fair private practice.

Applications, accompanied by Diplomas and Testimonials, to be forwarded to the Honorary Secretary, JOHN CARR, Esq., Mweelin, Achill, Newport, co. Mayo.

By Order, D. BROWNE, Clerk of Union.

Board-room, Newport, 26th August, 1874.

IRVINESTOWN UNION.

MEDICINES, &c., WANTED.—The BOARD OF GUARDIANS of this Union will, on WEDNESDAY, the 16th SEPTEMBER, consider Tenders for supplying, from 30th September, 1874, to 29th September, 1875, the Workhouse Infirmary and the several Dispensaries in the Union with Medicines, &c., of best quality, free of carriage.

All Empties returned at the Contractor's expense, and the amount charged in Invoice.

Forms of Tender may be had on application to me, or at Mr. TROX'S.

By Order, C. GRAHAM, Clerk of Union.

Board-room, Irvinestown, 24th August, 1874.

KELLS UNION.

TENDERS will be considered by the BOARD OF GUARDIANS on SATURDAY, the 19th instant, for Supplying the Workhouse Hospitals and Union Dispensaries with

MEDICINES AND MEDICAL APPLIANCES for One Year, from the 29th instant, which must be delivered carriage free, and the empties packed and removed at the Contractor's expense.

Printed Forms of Tender can be had at this Office.

Tenders will also be considered for the supply for same period of BOOKS, FORMS, STATIONERY, CLOTHING MATERIALS, &c.

By Order, NATH. LACY, Clerk of Union.

Workhouse, Kells, 1st September, 1874.

OMAGH UNION.

TENDERS will be received by me, up to Four o'clock P.M., on FRIDAY, the 11th of SEPTEMBER next, and considered by the BOARD OF GUARDIANS on the following day, for supplying the Workhouse and the Eight Dispensaries of the Union with

MEDICINES AND MEDICAL APPLIANCES for the year ending 29th September, 1875, free of all expense for carriage, packages, jars, bottles, &c.

Forms of Tender can be had on application here; no other will be entertained.

By Order of the Board,

WILLIAM J. MCKNIGHT, Clerk of the Union

Board-room, 22nd August, 1874.

GLENNAMADDY UNION.

The BOARD OF GUARDIANS of the above Union will, at their Meeting to be held on TUESDAY, the 15th day of SEPTEMBER, 1874, receive proposals for supplying the Workhouse and three Dispensaries with

MEDICINE, MEDICAL AND SURGICAL APPLIANCES, &c., for Twelve Months, from the above date.

Tenders, which must contain the names of Two solvent Persons willing to join in a Bond for the faithful performance of the Contract, will be received by me up to Twelve o'clock on the above-named day.

By Order,

EDMOND SMYTH, Clerk of Union.

Board-room, Glennamaddy,

1st day of September, 1874.

GLENTIES UNION.

DOOCHARY DISPENSARY DISTRICT.

The COMMITTEE OF MANAGEMENT of the above Dispensary District will, at the Meeting to be held at Lettermacaward Dispensary on MONDAY, the 14th day of SEPTEMBER, 1874, at Twelve o'clock noon, proceed to elect a properly-qualified

MEDICAL OFFICER for the District, at a Salary of One Hundred Pounds per annum, exclusive of Registration and Vaccination fees.

Applications, with Testimonials and Diplomas, showing that they possess the qualifications prescribed by the regulations of the Local Government Board, will be received by me up to Twelve o'clock noon on the above day.

By Order of the Committee,

JOHN O'DONNELL, Ballinamore House,

Dated 3rd September, 1874. Knockletra, Stranoriar.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 16, 1874.

## STUDENTS' NUMBER.

THE unsettled condition of the educational system of our profession which the demand for reforms and the keen competition of teaching and qualifying institutions have created has rendered more essential than ever our yearly budget of advice and instruction to the Student. From year to year important changes are effected, not only in the field of study of the Student, and in the method and nature of his examinations, but also in the arena for his employment after he has achieved his entry within the pale; and it is, we think, to the great advantage of the profession that these changes and the whole state of medical education should once in the year be brought prominently under the notice of our readers in an intelligible form. The primeval "Students' Number"—a reprint of incomprehensible official regulations and vapid paragraph puffs—is, like the Introductory Lecture, falling into disfavour, and at least one of our contemporaries joins with us in the effort to provide its readers with the practical information which they require.

We conceive it to be our rôle to place in the hands of the Student and his guardians the semi-confidential details, directions, and hints which College Regulations are not intended to communicate, and which are only known to those conversant with the various systems of education, examination, and qualification, and with the ultimate prospects of the Student.

The Student having—possibly by means of the hints derived from our pages—selected his College and Hospital, will doubtless provide himself with the full particulars of curriculum and educational arrangements in their full extent.

As we have, with the view of economising the space at our disposal, dispensed with all details which are contained in the advertisements of the various institutions, we beg to refer our readers to the announcements of each in our advertising pages, in connection with which the editorial information should be read. Our readers are thus, we trust, in possession of a complete *vade mecum* of the method and means of medical education.

## The Destination of the Newly-qualified Surgeon.

### THE PUBLIC SERVICES.

#### ARMY MEDICAL SERVICE.

IN by-gone years this Service was the prize of the profession, and was sought after by the best students of their year, because it ensured to the successful competitor a sufficient salary, a good social position, and a certain hope of promotion. Within the last decade the Service has, under the management of successive cobblers of the system, retrograded, and is now rather a resource for unattached students than an aspiration of the best class of students. Many changes have taken place which render it desirable that the expectant army surgeon shall, in Scotch parlance, "bide a wee" until he be definitely informed what terms of employment he may expect. Mr. Cardwell's Medical Unification Warrant, promulgated last year, has effected serious changes. Firstly, the title of "Assistant" is abolished, and all medical officers enter the Service as surgeons, and, at their first promotion, are called Surgeon-Major. Secondly, they are not permanently attached to any one

regiment: all medical officers are now on the general staff; all wear the same uniform, and are drafted as may be required for temporary service of a few months or a couple of years with any particular regiment. These arrangements have created extreme discontent in the Army Medical Service, especially as promotion, after fifteen years' service, is not definitely provided for; forage allowances are curtailed, and pay, after fifteen years' service, is reduced. It is easy to see that the position of an army surgeon, attached to-day, say, to a crack Hussar regiment in London, and next week, perhaps, to a squad of infantry on police duty at the dépôt at Ballinacree, will not be very desirable. Notwithstanding all these serious drawbacks, the student, after qualification, may very probably elect the Army Medical Service, and we therefore afford him all information as to his access to it.

The appointment of surgeon in the Army is open to all who can prove their claim to it by superior answering. Candidates for the British Medical Service must be unmarried, and not more than twenty-eight years of age. The competitive examinations are held at Chelsea, usually in the first weeks of February and August. The candidate is not required to produce any other qualification before presenting himself for examination than his licence to practise and certificates of registration, age, moral character, and physical capabilities.

The candidate must make a declaration that he labours

under no mental or constitutional disease, nor any imperfection or disability that can interfere with the most efficient discharge of the duties of a medical officer in any climate. His physical fitness will be determined by a board of medical officers, who are required to certify that the candidate's vision is sufficiently good to enable him to perform any surgical operation without the aid of glasses. A moderate degree of myopia would not be considered a disqualification, provided it did not necessitate the use of glasses during the performance of operations, and that no organic disease of the eyes existed.

Having received his diplomas in surgery and medicine, both of which are essential to his competition, the student is obliged to apply himself vigorously to the study of certain collateral subjects, which he does usually through the medium of a "grinder." He must perfect himself in chemistry, pathology, and comparative anatomy, and if he can throw a proficiency in botany and natural history and French and German into the scale, he will materially improve his position in the scale of merit, and establish for himself a character with the authorities for industry and scientific attainments.

The surgeon is subjected to three separate examinations within the first ten years of his service, each examination having a definite object—the first, to ascertain, previous to his admission into the Service as a candidate, his scientific and professional education, and to test his acquirements in the various branches of professional knowledge; the second, after having passed through a course of special instruction in the Army Medical School, to test his knowledge of the special duties of an army medical officer; and the third, previous to his promotion, to ascertain that he has kept pace with the progress of medical science.

For the first candidates will be examined in the following, and the highest marks attainable will be distributed as follows:—1. Anatomy and Physiology, 1000 marks; 2. Surgery, 1000; 3. Medicine, including Therapeutics, the Diseases of Women and Children, 1000; 4. Chemistry and Pharmacy, 100. Examinations will also be held in French and German (150 each), 300 marks; Natural Sciences, 300. The Natural Sciences will include Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with special reference to *Materia Medica*. The number of marks gained in both the voluntary subjects will be added to the total number of marks obtained by those *who shall have been found qualified for admission*, and whose position on the list of successful competitors will thus be improved in proportion to their knowledge of modern languages and natural sciences.

The candidate having sent in his papers, and followed them to London, meets his competitors at Chelsea.

For the first two days of his examination he is employed in penning answers to printed questions; for the third and fourth days he is examined *viva voce* on all subjects; and on the fifth and sixth days he is tested by the diagnosis of disease at the bedside in the hospital, by the application of surgical apparatus, and by operations on the dead subject. This trial finished, the successful candidates (varying in number from fifteen to thirty, are selected.

#### SERVICE ON THE WEST COAST OF AFRICA.

A certain number of candidates, whose answering has been satisfactory, but not sufficiently so to entitle them to a place, were formerly offered appointments on the West Coast of Africa, but recently they have been appointed to the Naval Medical Service, as vacancies on the Coast have not existed for some time. These situations, while they

are subject to strong objection on the score of the deleterious nature of the climate, possess some advantages for those whose health can resist its influence. The districts comprised under the West Coast Districts are Sierra Leone, Gambia, and Cape Coast Castle. If the candidate accepts the appointment he is sent out at once, without the period of probation to which others are subjected at Netley Hospital. He is allowed to spend a year at home, on full pay, for every year spent in Africa, and the entire period at home and abroad should count as service for pension.

#### PROBATION AT NETLEY HOSPITAL.

The competitor who has been so fortunate as to obtain a place in the ordinary Service is not allowed to join a regiment at once. He is obliged to undergo a probation of four months at Netley Hospital, near Southampton, where he is compelled to attend the following lectures—viz.: Hygiene, by Dr. Parkes; Pathology, by Dr. Aitken; Military Surgery, by Dr. Longmore; and Clinical and Military Medicine, by Dr. Maclean. The lectures on Military Surgery include gunshot and other wounds; arrangements for the transport of wounded; duties of army surgeons in the field, during sieges, on transport, &c., and other special subjects. Those on Military Medicine refer to the tropical and other diseases of the British possessions and colonies, and to the losses by disease. The lectures on Hygiene relate to the examination of water, air, food, clothing, &c., of the soldier, his duties and exercise, and the circumstances affecting his health, meteorology, statistics, and prevention of disease. The lectures on Pathology have reference chiefly to the scientific examination of tropical diseases, and of the other complaints which the army surgeon is especially called on to investigate. The candidates also attend the wards of the hospital under the Professors of Medicine and Surgery, to make themselves acquainted with the system of recruiting, and the modes of keeping the Army Medical Returns. They are also called on to make post mortem examinations, to operate on the dead body, and to pass through laboratory practice on the modes of recognising the qualities and adulterations of food, and on microscopic examination of morbid tissues, and adulterations of food, &c. During his preliminary training here the student is understood to be in Her Majesty's Service; he wears uniform, is under military discipline, and receives pay at the rate of five shillings per day, and two shillings per day for lodging money, if he be not provided with lodgings in the hospital. A sum of money equal to the half-yearly interest on £1,200, the surplus from the "Herbert Memorial," is at the end of each session awarded to the candidate who has the highest number of marks, the fortunate young man who wins this "Blue Ribbon of Netley" being tolerably certain to be well provided for. At the termination of the four months he is again examined in the subjects in which he has been instructed during that period, his marks are added to those obtained by him at the competitive examination, and his position on the list of merit determined by the total. Successful candidates are now eligible to be gazetted to a regiment, or employed on the staff, and enjoy all the rank and honour, pay and privileges, of surgeons, as provided by the regulations.

Thus it will be observed that the first, or Chelsea examination, simply admits the candidate to the Service, and the conjoint result of it and the Netley examination determines his order of merit.

#### LIFE AT NETLEY.

The medical candidates, as the surgeons are called until they have passed out of the hospital by their second examination, are congregated at Netley, in addition to the com-

missioned officers who may be there. During the period of his residence at the Army Medical School each candidate will receive an allowance of 5s. per diem, with quarters, or 7s. per diem without quarters, to cover all cost of maintenance; and he will be required to provide himself with uniform (viz., the regulation undress uniform of a surgeon, but without the sword). Each candidate has to pay £5 towards the mess fund, one half on his arrival and the remainder when he has passed his second examination. He is then a member of the mess, and entitled to dine at any time during the remainder of his service. The cost of dinner is 2s. 4d. daily, not including wine, and of breakfast from 10d. upwards.

#### THE PROMOTION EXAMINATION.

But there is still one other which *must* be passed before he is promoted to full surgeoncy, and *may* be passed at any time after five years' service.

A series of printed questions will be sent by the Director-General to the principal medical officers of stations where surgeons may be serving, who will deliver these sealed questions to the surgeons, and see that they are answered without the assistance of books, notes, or communication with any other person. The answers are to be signed, and delivered sealed to the principal medical officer, who is to send them, unopened, to the Director-General, together with a certificate from the surgeon of the regiment, or other superior medical officer, that the surgeon has availed himself of every opportunity of practising surgical operations on the dead body.

The surgeon will also be required to transmit a medico-topographical account of the station where he may happen to be, or of some other station where he may have been resident, or else a medico-statistical report of his regiment for twelve months.

If the Examining Board and the Director-General are satisfied with the certificates and answers, and with the report, the surgeon will be held qualified for promotion.

#### GENERAL OBSERVATIONS.

The bachelor surgeon, commencing with an income of £182 10s., in addition to quarters, coals, and candles, has the use of a soldier servant for 10s. a month, and 15s. for washing. Mess bills and subscriptions vary according to circumstances, high in the cavalry, rifle brigade, and certain line regiments, at home, but moderate in the artillery and line generally; about £10 would represent the outlay. Some can live cheaper by taking breakfast in their own room—the bed in one corner, the tub in another, not a wholesome arrangement. Respectable uniform, a gentlemanly appearance in dress must be maintained, and the servant clad for everyday work besides to wait at mess. Being on the staff, as a rule, is comparatively cheaper for married men, but the bachelor, friendless and homeless, will find there is nothing better than a good line regiment, especially where the colonel and the surgeon pull together, and the latter takes a fair share of work. Those who marry early without means should remember they may reach the age of forty as surgeons with a large family to keep and drag about on an income under £300, deducting income-tax. The more pursuits and accomplishments a medical officer has the better, especially if at the same time he is a good doctor and a gentleman. For the combatant officer a position is made; the medical man makes his own, as in civil life. The Army would attract good men if the dead-lock and stagnation were removed by optional retirement at £1 a day after twenty years' service. Unless the medical officer has private means he should not remain a day in England.

The daily rates of pay of medical officers of the Army are as follows:—Pay daily: Surgeon-General down to Surgeon-Major, £2 10s. to £1 10s. a day, according to length of service; Surgeon-Major 17s. 6d., after fifteen years' service £1, after twenty years' service £1 4s., after twenty-five years' service £1 7s.; Surgeon, on appointment, 10s., after five years' service 12s. 6d., after ten years' service 15s., after fifteen years' service 17s. 6d.

Medical officers have a right to retire on half-pay after twenty years' service; Surgeons-Major or Surgeons shall be placed on the retired list at the age of fifty-five.

Surgeon-Major of twenty years' service rank as Lieut.-Colonel; Surgeon-Major under twenty years' service rank as Major; Surgeon of six years' service rank as Captain; Surgeon under six years' service rank as Lieutenant.

Forage is granted to medical officers for such number of horses as are necessarily kept by them for duty.

It will be understood that this latter privilege is illusory, because a Surgeon-Major (though ranking as a mounted officer) may not have duty for a horse, and a surgeon who may have necessity for a horse to-day may be moved to-morrow to a post where no horse is requisite, and will have to sell or keep the animal at his own risk.

The official regulations may be obtained by application to the Director-General, Army Medical Department, 6 Whitehall Yard, London, S.W.

#### INDIAN MEDICAL SERVICE.

The regulations, subjects, and times for examination are the same as for the Army Medical Department. Passage allowance to India on appointment will be given, or a passage provided. When passages are provided on board the Indian troop ships, a charge for messing will be made at the rate laid down in the Royal Passage Warrant of 1865. Pay at 10s. a day will be allowed from date of passing final examination at the Army Medical School.

Indian allowances and time of service for pension will reckon from the date of arrival in India.

Surgical instruments are provided in India by the Government for the use of medical officers.

The pay of medical officers in the Indian Service is much better than at home, and, if unmarried, the cost of living not greater. Moreover, the medical officer frequently holds lucrative civil medical appointments which afford him a handsome increase of income. Without doubt, to a healthy, temperate, unmarried man the Indian Service is greatly preferable to that at home, but to a delicate person, or one burthened with a wife and children, the advantages are questionable.

For official regulations of the Indian Medical Service apply to the India Office, Whitehall, London, S.W.

#### NAVAL MEDICAL SERVICE.

In applying to be admitted as an Assistant-Surgeon in the Royal Navy it is merely required to address a letter to the Secretary to the Admiralty, stating that you are in possession of a diploma from such a College—naming it; that you are desirous of being admitted as a candidate; when, if there are any vacancies, you will be informed when you will be required to present yourself at Somerset House, London, for examination.

The subjects and method of examination and the subsequent service at Netley are in all respects similar to those referred to above under the head of Army Medical Department.

Having passed your examination you will, in the course of the following day, receive your appointment as acting Assistant-Surgeon to one of her Majesty's ships, either for service on board that ship, or for service on shore, at one of the naval hospitals—Haslar or Plymouth. You will at the same time be informed that you are granted two or three weeks, as you may require, leave of absence, to enable you to provide your uniform and appointments. These you can get at any of the naval outfitters.

The expense of an Assistant-Surgeon's uniform is about £47 5s. You must also provide yourself with a set of surgical instruments, which will cost you from ten to fifteen guineas. All kinds of underclothing, towels, handkerchiefs, &c., may be purchased much more advantageously from a regular dealer in those things than from any naval outfitter.

#### ADVANCE OF PAY ON JOINING.

The monthly mess subscription varies in ships, according to the station they are on, from £2 10s. to £3 10s. per month. This subscription does not include anything for wine or liquors of any kind. Whatever amount of these you may consume will be paid for by you separately, at the end of each month or quarter. But as all wines are permitted by sanction of the Admiralty, to be shipped free of duty, you drink them so much cheaper on board than you could the same qualities of wine on shore. The monthly subscription of say £3, with the Government allowance of £11 3s. 8d. per annum to each member in lieu of provisions, is generally found sufficient to meet all ordinary expenses of messing.

It is the custom in all ward-room messes to have an extra dinner on two days of the week—generally on Monday and Thursday. The days so selected are styled "field-days." It is on these days that guests are invited to dine by the mess. The guests thus invited are called public guests, and such invitations entail no extra subscription from any one, except for the extra wines consumed. It is usual to invite the captain, and other superior officers that may be on board, once a week; the other public guests are so many of the junior officers of the ship; and, if in port, officers of the sister service, and other public functionaries. The captain, or admiral, if there be one on board, usually has two or three ward-room and two or three gun-room officers to dine with him on every other day of the week than that on which he dines in the ward-room. Any member of the ward-room mess inviting a private friend to dine with him on board pays usually from 2s. 6d. to 3s. 6d. according to the rule of the mess) for his friend's dinner, in (addition to any extra expense for wine.

The foregoing are the whole of the ordinary and extraordinary expenses of messing in the ward-rooms of her Majesty's ships, and which should not, with drinking a reasonable quantity of wine, beer, &c., exceed fifty guineas per annum.

Officers in the Navy, wherever they may be serving, can remit, by the paymaster of the ship, without any expenses, any portion, or the whole, of their pay that may be due to them on the last day of each quarter.

#### SERVANTS.

Assistant-Surgeons are allowed only half a servant each, or in other words, a servant between two of them.

These servants are entered on the ship's books with the rating of officers' servants. Their pay from the Admiralty is about £17 per annum and their provisions; and where they are well-conducted, attentive lads, it is usual for their masters to give them 10s. a month, which makes their pay up to about £29 per annum.

The pay of naval medical officers has hitherto been the same as for their military brethren.

#### PENSIONS OF MEDICAL OFFICERS.

Besides the half-pay awarded to medical officers, there are three good-service pensions of 10s. each per diem awarded to the three inspectors-general who have completed the longest and most meritorious service.

There is also one Greenwich Hospital pension of £30 per annum awarded to a deputy inspector-general.

There are fourteen other Greenwich Hospital pensions of £50 each per annum, awarded to those fourteen deputy Inspectors-General, Staff-Surgeons, and Surgeons who are considered by the Admiralty to be most deserving of them.

#### PROMOTIONS.

An Assistant-Surgeon having served three years may be examined as to his qualifications for promotion to the rank of Surgeon. If he be serving abroad he may, if he wish it, be examined provisionally by an Inspector or Deputy Inspector-General and three Surgeons; and as soon after his arrival in England as may be convenient for him to present himself at Somerset House for his regular and final examination. To enable Assistant-Surgeons to pass this examination satisfactorily, they are granted, on application, two months' leave of absence to prepare themselves for it. The use of passing the provisional examination abroad is, that the Assistant-Surgeon, having served five years, is then eligible for promotion into any vacancy that may occur, as Acting Surgeon.

If the vacancy occurring shall have been caused by the death of an officer of superior rank, this promotion of Acting Surgeon will be confirmed as Surgeon on passing the regular examination at Somerset House. If the vacancy has occurred from any other cause than that of death, the Assistant-Surgeon appointed to fill it, whether he may have passed only provisionally or finally, will be appointed only as Acting Surgeon until the pleasure of the Admiralty be known, who may either confirm him in it, or supersede him by the appointment of a Surgeon from half-pay.

Surgeons are promoted to the rank of Staff-Surgeons on twenty years' service provided that ten years have been completed since passing for the rank of Surgeon.

By an Admiralty regulation, dated the 12th of July, 1867, promotion to Staff-Surgeon is to be open to officers for distinguished or special services, although they may not have completed twenty years' service.

#### PRIZE MONEY.

Medical officers share in the proceeds of all prizes captured from the enemy, of captures and seizures under the several Acts of Parliament passed relating to the revenues of Customs, and of trade and navigation, for the abolition of the slave trade, for the capture and destruction of pirates and piratical vessels, and of the rewards conferred for the same, as also in the awards of all salvage granted to the crews of her Majesty's ships and vessels of war, with other officers of corresponding ranks.

The full and half-pay of Naval Medical Officers is in accordance with the following scale:—

Full-pay: Surgeon—Under five years' service, 11s.; under eight years' service, 12s. 6d.; under eleven years' service, 14s.; under fourteen years' service, 15s. 6d.; above fourteen years' service, ditto, 17s. Staff-Surgeon 2nd class—On promotion, or under fourteen years' service, 18s.; ditto, or under seventeen years' service, £1; and for each additional year of service, 1s. a day more until the maximum is reached—namely, £1 2s. Staff-Surgeon—On promotion, or under twenty years' service, £1 3s.; ditto, or above twenty years' service, £1 4s.; and for each additional year of service, 1s. a day more until the maximum is reached—namely, £1 10s.

Deputy Inspector-General and Inspector-General from £1 11s. to £2 10s. Half-pay: Surgeon—6s. to 17s., according to service. Staff Surgeon 2nd class—11s. to 14s. Staff Surgeon—16s. to 18s. 6d. Deputy Inspector-General and Inspector-General, £1 1s. to £1 18s.

#### POOR-LAW MEDICAL SERVICE.

A YOUNG qualified practitioner, indisposed to be an assistant, and desirous of commencing general practice without investing any money in purchasing a succession, may, perhaps, obtain a Poor-law appointment, though he should scarcely expect to obtain a livelihood from this inadequately remunerated employment.

##### ENGLISH POOR-LAW MEDICAL SERVICE.

Prior to the passing of the Metropolitan Poor Act of 1867 the English Poor-law Medical Service may be said to have been in the hands of the guardians, supervised by the Poor-law Board. Each parish in England and Wales had its guardians of the poor, and these parishes were grouped together to form unions. The unions were divided into districts for medical relief. Union medical officers, therefore, have the care of a district, or sometimes the care of the workhouse of the union—sometimes of both. The officer was elected by the guardians, and the appointment approved by the Board. He was required to have both a medical and surgical qualification. In some instances these were specified, but almost always the London College of Surgeons and Apothecaries' Hall were the two most favoured diplomas. For this reason London students will still continue to take these qualifications, whatever else they may add to them. But the L.R.C.P. Lond. is now recognised as a full qualification, both medical and surgical. The salaries of Poor-law appointments are very low. They are, however, sought after by young men as a means of getting into practice, and are often almost obligatory in the country to prevent fresh opposition being introduced. The Metropolitan Poor-law Act, 1867, assimilates the Poor-law, so far as London is concerned, to that of Ireland, and the Poor-law Board is now merged in the new Local Government Board. It has established in London asylums and dispensaries, and distributed the cost of supporting them over the metropolis. Under the new Public Health Act many Poor-law officers have been also appointed medical officers of health.

#### THE IRISH POOR-LAW SERVICE.

THE newly-qualified medical practitioner who may elect to try his luck in the Irish provinces sets his hopes, in the great majority of instances, upon obtaining one or more Poor-law medical appointments in some district where there is hope of private practice. There are 163 workhouses and about 793 dispensary medical officers, besides apothecaries. The number of vacancies that occur annually averages 100. The average salary in this service is now about £103 15s.; and when it is taken into consideration that in the vast majority of rural districts it is necessary to keep a horse, and in some a boat as well, the average area being from forty to sixty square miles, it is plain that there will not be a very large margin left from the public emoluments. The medical officer is also *ipso facto* the registrar of births, marriages, and deaths, and the medical officer of health for the district, under the Public Health Act, passed last session. The former office, in country districts, seldom yields more than £10 a year, and often not half that amount, and the emoluments of the latter appointment are as yet unknown.

The medical officer is also vaccinator for the locality, and is required to vaccinate every one who wishes to come. For each patient his fee of 1s. is paid along with his salary by the guardians, and the sum total of these fees varies, according to the populousness of the district, from £2 to £50, an average for the provinces being about £5. Despite the miserable salary, and the very many discomforts of dispensary life, these appointments are generally eagerly sought for—firstly, because they afford the new comer a certain, though hardly-earned salary, to supplement his private earnings; and, secondly, because, if not secured by the new comer, they would of necessity bring a competitor for practice into the field, and inasmuch as private income is of far greater import than public earnings, country medical practitioners are obliged to undertake the public duty in order to save to themselves the monopoly of their private emoluments.

##### APPOINTMENT.

The qualifications required by the Poor-law Commissioners are a Licence in Surgery or a Diploma in Medicine, and a Diploma in Midwifery; the candidate must also be twenty-three years of age.

The appointment lies with the Dispensary Committee, who elect by vote. As politics and religious feeling run high in Ireland, these elements enter into the election of Poor-law medical officers. Family interest also possesses great weight.

The candidate will do well to bear these facts in mind, as his personal attendance on the day of election will be required, and whatever other qualification he may have, he will then find that his compatibility in these respects with the majority of the committee is essential; and, accordingly, he had better first make himself acquainted with the local peculiarity, whatever it may be, before he enters on his candidature, otherwise, in all probability, any expenditure that he may make in the matter will be simply thrown away. We may here observe also, that in very many instances the appointment is virtually made before the advertisement appears for a medical officer, in which case also candidates are put to unnecessary trouble and expense under false pretences.

##### CONTROL.

Each district is under the direct control of a committee composed of the neighbouring landholders, the appointment of medical and other officers is made by this committee, and the entire management of the district is under their control. Their acts are, however, subject to the approval of the Local Government Board, who have the power either of interposing their veto on any appointment, or even of expelling an officer by a "sealed order," without trial or accusation, or without the resource of appeal or investigation. This salary is paid by the Board of Guardians, and no increase can be made in the amount without their assent and that of the Local Government Board. Under the late Sanitary Act the committee may recompense the medical officer for special services, such as those during an epidemic of cholera, or for sanitary reports. The number of unions in Ireland is 163, to each of which is attached a medical officer, who is appointed and controlled by the Board of Guardians in the same manner as the dispensary surgeon is by his committee. The salary is usually better than that of the dispensary doctor, and the duties of a more easy and satisfactory description, inasmuch as the duty is confined to daily attendance at the workhouse hospital, and no night visits out of doors or any long journeys across the country are involved.

## DUTIES.

The duty of the dispensary doctor is twofold. He is to attend his dispensary on a given day or days in the week. Frequently there are two dispensaries in the district, separated from each other by several miles, and he will have perhaps to attend two days a week. He has also to visit at any hour of the day or night a sick person for whose relief a visiting-ticket has been issued by a member of the committee or by the relieving officer, and to continue his attendance as often as may be necessary until a termination of the case. Moreover, he has a great many registry books to keep, and a multitude of returns to make, and in the majority of districts he has to make up all the medicines for the poor.

The pressure of these duties is in the greatest degree dependent on the good will of the members of his committee. If the medical man be a favourite with his masters they will give him very little trouble with "scarlet runners," as the visiting tickets are, from the colour of the paper on which they are printed, humorously called, and will be unwilling to trouble him even with cases deserving of personal attendance.

If, on the other hand, it is his misfortune to come in contact with some of the half-bred committee-men, who know nothing of the treatment fit for an educated gentleman, or cherish a personal spite, the discharge of his duties may become simply unbearable. He may be peremptorily summoned, in any weather, at any hour, and to any distance, to a case which he may probably find to be altogether trivial, or to a person whom he may know to be perfectly well able to pay—aye! even the committee-man's own brother or daughter.

## SUPERANNUATION.

By a recent Act of Parliament a Poor-law medical officer may now receive a pension not exceeding two-thirds of his salary on being incapacitated, from illness or old age. This grant is strictly at the discretion of the guardians; nevertheless, it has been given in most cases in which physical incapacity has been clearly proved. It is, however, at best a miserable resource, and can by no means be calculated upon as a provision for old age. There are now 65 ex-medical officers receiving superannuation allowance whose average term of service before pension was 20 years, and whose average allowance is £64 15s. Their average age at retirement was 63. All official information may be obtained of B. Banks, Esq., Local Government Board, Custom House, Dublin.

Complete information as to fees, emoluments, duties, and appointment of Irish Poor-law medical officers will be found in the "Irish Medical Directory" for 1874.

## SURGEONCIES IN THE MERCANTILE MARINE.

THE appointment of surgeon in sea-going vessels is much sought after by young surgeons who are desirous of seeing a little more of the world than school, college, or home have shown them; but the office is seldom held for more than a few years. These appointments are almost uniformly in the gift of directors and secretaries of companies, and of the owners themselves, with whom, as may be believed, personal influences are a better recommendation than any professional qualification.

The Cunard and other American mail lines select their surgeons through the interest of owners and managers. The English ships are bound to carry English medical officers, and American ships American surgeons. The pay varies from

ten guineas per month upwards, and the arrangement may be terminated by the surgeon at any time that the ship is laid up, unless he has signed special articles.

The West India Mail Service admits candidates only between the ages of twenty-two and forty. A regular curriculum similar to that required by the licensing bodies is necessary, and a special examination in climatic disease is sometimes administered to the candidate. At entry, surgeons are requested to join vessels in the West Indies or Brazils, relieving surgeons longest out, and being themselves relieved in turn.

## EMIGRATION SERVICE.

THE Emigration Commissioners are now reducing their staff, and making no appointments to vacancies as they occur. Many of the trading ships which carry emigrants to New Zealand and Australia take surgeons only on their outward voyage, and call at China for silks and other freight on their way home. Surgeons to these vessels are paid only £25, and, finding it impossible to obtain a passage home again, are compelled to settle in the colonies, which are accordingly over-stocked.

## EUROPEAN COMMUNITIES.

THERE is a growing demand for surgeons for small European colonies, and several desirable appointments have been recently made. A number of colonists feeling the want of efficient medical advice subscribe an annual guarantee salary of from £200 to £800, allowing the appointed candidate to make what fees he can by private practice in addition. Candidates in all cases are required to speak French, and a knowledge of German is generally necessary.

## NEW AUSTRALIAN SETTLEMENTS.

UNDER the late Land Settlements Acts of the Australian colonies, a great impulse has been given to the opening of new districts, which require the services of competent surgeons. The chief agent through whom these arrangements have been carried out is Mr. Thomas W. Powell, of Clare, with whom the representatives of the settlers communicate. Mr. Powell conducts his English business through Dr. Baxter Langley, of London. The usual arrangement is based upon a guarantee of £200 a year, with horse, and free quarters for three years, with freedom to practise. These appointments are worthy the attention of those who do not object to colonial life, an income of £1000 a year being readily made by a steady, well-qualified young man.

## The Student's Life, Education, and Qualifications.

## THE GENERAL MEDICAL COUNCIL.

## REGISTRATION OF STUDENTS.

To this body is entrusted the supervision of Medical Education, and it has made a number of recommendations, the majority of which have been accepted by all the Examining Bodies, and are, consequently, found in their regulations. The student has, therefore, nothing to do

with the Council, except that he must take care to be duly registered as a Student of Medicine, *at the commencement of his career*, at the offices, 315 Oxford Street, London, in Dublin, or in Edinburgh. He must previously have passed a preliminary *Arts Examination*. In order to effect this, each student should apply according to a form accompanied by a certificate of his having passed such examination, the same to be lodged with the Registrar, who will thereupon enter the name in the Students' Register, and issue a certificate to that effect.

The intention of this registration is to ensure that the student shall occupy four years in medical study, which is, theoretically, the period which must be devoted to his education before his entry to the profession. In England this requirement is frequently satisfied by a nominal service for the first year under a general practitioner, or in a provincial hospital or dispensary, and the actual period of medical study is often really three years.

In Ireland the majority of the licensing bodies do not insist on the passing of Arts Examination before registration, nor do they insist on four years' study from any fixed date. Generally speaking, the student's name is forwarded to the Registrar of the Branch Council by the public officer of his school, and therefore he gives himself no trouble about it, and, as the duty is very irregularly performed, the Register of Students for Ireland is very imperfect, and wholly unreliable.

#### REGISTRATION OF PRACTITIONERS.

All duly qualified Physicians, Surgeons, Medical Graduates, and Apothecaries are required by the Medical Act 21 and 22 Vic, c. 90, to be registered before they can hold any public medical or surgical appointment, or issue valid medical certificates.

The medical registration of any practitioner may be effected, on application, in writing (according to a form to be had at either of the Branch Offices or in London), and producing, or transmitting with such requisition the *Diplomas* to be registered, and also paying or remitting the fee, which is regulated by the Medical Council, viz., £5 for first registration, and 5s. for every qualification which may be subsequently added. Each practitioner is entitled to receive a copy of the official Medical Register free on application.

#### THE CAREER OF THE ENGLISH MEDICAL STUDENT.

SEVERAL courses are open to the young gentleman who has decided to enter the medical profession in England, whether he fulfil his curriculum in London or in the provinces. As the latter course is generally determined by local causes, we will first of all point out a few things that concern both London and provincial medical students.

#### APPRENTICESHIP.

The Society of Apothecaries, hitherto fettered by Act of Parliament, required an apprenticeship. The apprentice was, however, of late years allowed to fulfil part or all of his curriculum during his apprenticeship, and under the Act passed last session we presume the apprenticeship system will gradually pass away. The apprenticeship system, when carried out in a liberal manner, was not

without its advantages. In the early part of his pupilage the apprentice not only learned practical pharmacy, and became acquainted with the more generally used articles of the *materia medica*, but was often assisted in preparing for the preliminary examinations. Moreover, he prepared himself to take, should he ever wish to do so, the post of assistant to a general practitioner, as the experience he had thus acquired would procure him a situation in preference to prizes, gold medals, and even university distinctions. Again, this experience was of the very highest value on settling in general practice.

#### PUPILSHIP.

Supposing that the plan of apprenticeship be rejected, a young man can instead become the *pupil* of some one in practice. This is frequently done by those who aim at the higher branches of practice. An experienced practitioner, whether a physician or surgeon, who will superintend or direct a pupil's studies, offers great advantages, and we think that those who can afford a pupilship will not regret the expense of providing themselves with such a guide.

#### THE PRELIMINARY EXAMINATION.

We would remind the student that some preliminary examination in arts, which is recognised by the General Medical Council, *must* be passed by him *before* entering a hospital. The subjects must include Latin and mathematics. There are numerous preliminary examinations, of which a list may be obtained. For the *English Medical Student* we should say that, *ceteris paribus*, the Matriculation Examination of the London University is the best. We do not deny that it is more severe than most or all of the other preliminary examinations, but, nevertheless, we would recommend those who have sufficient ability and the time to prepare for it, to matriculate, as they will thereby be enabled hereafter, if they should desire so to do, to present themselves for examination for the degrees in Medicine or Surgery conferred by this University. It is also accepted by the College of Surgeons in lieu of the arts examination otherwise imposed on candidates for its Fellowship.

Should circumstances deter the student from offering himself for the matriculation, he will find an easier standard in one or other of the preliminary examinations for the Fellowship or Membership of the Royal College of Surgeons of England, or that of the Society of Apothecaries. Full information with regard to the dates and subjects of examination, or the list of examinations recognised by these bodies, may be obtained from the Secretary to the College of Surgeons, Lincoln's Inn Fields, or from the Beadle at Apothecaries' Hall, Bridge Street, Blackfriars.

As soon as the preliminary examination has been passed, or, at any rate, before commencing hospital study, it will be necessary for the student to register at the Medical Council, as the commencement of the course of professional study will not be recognised by any of the qualifying bodies as dating earlier than fifteen days before the time of registration.

#### HOSPITAL STUDY.

A pupil may enter at any of the London Hospitals without having passed through either a pupilship or an apprenticeship. Provided he has passed a preliminary examination, he has only to pay his fees and hear the

Introductory Lecture on the 1st of October, when he is admitted at once to all the privileges of a medical student. He should decide on the diplomas he requires, and guide his studies accordingly. Most schools have now a composition fee, entitling to all lectures and practice required for the ordinary qualifications in medicine and surgery. They also mostly have another sum, very little higher, entitling the student to *perpetual* attendance on all lectures and hospital practice. It is best to take the perpetual ticket, as all contingencies are thereby provided for. The fees are generally payable in instalments, at the commencement of each winter session. The Dean will always forward details as well as any special information which a student may need.

#### RESIDENCE.

The student who comes to London to fulfil his curriculum at a metropolitan school, generally requires lodgings, unless he can live with relatives or friends, which is of course better. Comfortable furnished apartments are to be had in respectable streets near all the hospitals. Two brothers or two friends can, of course, do this a little less expensively than one. The price varies with the season and the quality of the rooms. It should be mentioned that one or two of the Medical Schools (St. Bartholomew's, University College, King's College) have collegiate institutions in connection with them, where rooms may be had instead of taking lodgings. At many schools, also, some of the lecturers receive pupils. Special information on this subject may be had on application to the Dean or any of the lecturers.

#### PRIZES AND SCHOLARSHIPS.

As to contending for prizes, there are differences of opinion. Diligent attendance on the classes and in the wards will enable the student to store his mind with knowledge fitting him for his profession, and this should be his first aim. Gold and silver medals are honourable distinctions, but only secondary ones. Still, we would not discourage those intending to compete. It should be remembered by all students that the true end and aim of their studies should be to make them good doctors. They should study diligently to make themselves such, and there can be no reasonable objection to their striving for, in addition, an extra good standard in any subject or subjects in which they feel they are qualified to obtain it. In so far as prizes and scholarships encourage the study of particular branches there can be no objection to them. Nearly every student excels in some subjects more than others, and a prize is an additional incentive to arduous but otherwise unrequited studies. The only danger is that they should become too special, and encourage one branch of study at the expense of the others. Students have often failed at examinations where the number of subjects was numerous through giving undue attention to some favourite branch of study.

Competition for appointments to dresserships and other offices, where much practice is seen, stands on a different footing. No prizes can equal such posts; and the possibility of getting them should influence largely the choice of a school. In some schools they must be paid for. In others the diligent gain them without extra expense. The student having selected his hospital and school, has chosen

his teachers. We have only to remind him that, however able they may be, the result depends chiefly on his own application.

#### CURRICULA AND QUALIFICATIONS.

As to these, the information most valuable to students may be divided into two parts:—

I. The regulations with which they must comply before they can present themselves for examination to any of the licensing bodies.

II. The means that exist to enable them to do so. In the first division are to be placed the regulations of the corporations; in the second, some account of the many schools of medicine and hospitals where professional education can be pursued. A natural supplement to this information is a brief sketch of the career open to young men after they have obtained their diplomas, especially in the public services.

In accordance with this plan, we proceed to consider—first, the Regulations of the Qualifying Bodies. These may also be divided into two classes—I. The Universities; II. The Corporations.

#### THE UNIVERSITIES.

##### OXFORD AND CAMBRIDGE.

The older English Universities have lately opened their doors much wider than hitherto, without, however, losing any of their prestige. Those who propose to follow their course of education need not any longer enter at any particular college or hall, though it will be most probably long before lodger students become numerous. There are advantages in a collegiate life that will not willingly be given up by those who can afford it.

##### THE LONDON UNIVERSITY.

For those who would not like or cannot afford to enter a college, it is perhaps preferable to graduate at the University of London. The medical degrees of this University have now obtained a reputation second to none. No student can therefore propose to himself a higher qualification. The training is rather longer than is required for the diplomas of most corporations. The examinations are very stringent, but in after years the student will feel the gratification of having obtained such a degree. Every student is required to go through the full course of hospital studies *after* he has passed the matriculation examination. It is therefore very important that he should matriculate before entering a medical school, otherwise he will be compelled to stay more than four years at a hospital, as the University regulations require four years of hospital study and attendance on lectures *after matriculation*. It is therefore desirable he should matriculate before entering a medical school. The matriculation examination of this University is accepted as a preliminary by the Medical Council, and therefore the labour bestowed in preparation will serve the student's purpose even if he do not proceed to a degree.

We should also strongly recommend those students who intend to graduate at the London University to so arrange their studies as to pass [the preliminary scientific examination *before commencing their regular medical studies*, taking a preliminary year for the purpose of preparation. In this way much knowledge will be gained which will go to clear the way for his first year's studies which would otherwise be much encumbered. The medical degrees of the University are Bachelor and Doctor of Medicine, and Bachelor and Master in Surgery. Degrees in science are also now obtainable. There are at each stage of the graduate's career examinations for honours, which afford the student the opportunity of gaining highly-prized distinctions in various branches. There are

prizes, exhibitions, and scholarships for the most successful.

#### UNIVERSITY OF DURHAM.

The degrees of Bachelor and Doctor of Medicine are granted by this University, as is also the degree of Master of Surgery, generally when candidates present themselves, but this does not often occur. There is also a Licence in Medicine, for which residence is not essential.

From the Universities we pass to the other bodies that are empowered to give authority to practise.

#### THE CORPORATIONS.

##### THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

**THE FELLOWSHIP.**—The Fellowship of this College is attainable only by election, and no one can be proposed who is not a member of at least four years' standing.

**THE MEMBERSHIP.**—A person may become a Member of this College without holding a degree in Medicine, or indeed, any diploma. This is not very often done; for the Membership gives no right to the use of the title Doctor, though some Members not possessed of a degree style themselves so. This is, however, a direct violation of the rules of the College, to which a member pledges himself on admission. The curriculum extends over four years.

Graduates in Medicine of any *British* University are admitted to an examination for the Membership. Such graduates are exempt from some parts of the examination—*e.g.*, anatomy and physiology. Even foreign graduates of accredited universities have no difficulty in being admitted to examination.

**THE LICENCE.**—This diploma authorises the holder to practise his profession as a Licentiate of the College. Unless a graduate of some University, he is forbidden to use the title of doctor, but we regret to say many do so. It was regarded at first as a diploma for the general practitioner, intended to supersede that of the Apothecaries' Company. The examination is conducted by specially appointed examiners, and is complete in the several departments. The following by-law was enacted on August 4, 1874:—

"Every candidate for the College Licence who shall commence his professional study on or after the 1st day of October, 1874, will be required to produce satisfactory evidence of having completed the course of study in accordance with the by-laws and regulations of the College, and to pass the professional examinations conducted by the Conjoint Examining Board."

The by-laws to which this refers can be obtained on application to the Registrar at the College.

Nearly seven years ago the most important change occurred that has ever taken place in reference to the qualifications of general practitioners. This licence of the London College of Physicians was then recognised by the Poor-law Board as a qualification *in surgery as well as medicine*. Consequently, this single diploma is sufficient to enable anyone to take a Poor-law appointment. Any one contented with the diploma of L.R.C.P. Lond. would thus have all he needed as a legal qualification.

##### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

No College has exercised more influence over the profession than this. Without M.R.C.S it is not easy to obtain any English surgical appointment. Its membership, although no longer essential, yet carries great weight in a parish appointment. For this reason most English students take this diploma, which, together with a medical qualification, suffices for every purpose of the general practitioner. The College gives three diplomas, the Membership, Fellowship, and a diploma in Midwifery, which last is, however, mostly confined to those who are already members.

**THE MEMBERSHIP.**—This diploma gives no vote in the affairs of the College. It is only a licence to practise, and corresponds with the licentiatehip of the Edinburgh and Dublin Colleges.

In future, candidates for the diploma will be examined in the Practice of *Medicine*, and also in the practical employment of splints, bandages, and other surgical appliances. There are now two examinations for the Membership, the Primary and the Pass.

**THE FELLOWSHIP.**—Members of long standing can be admitted by election. As, however, this grade is also to be obtained by examination, which is preferred by many, as of greater value, this is the usual manner of taking the F.R.C.S.

A Member of the College of eight years' standing is admitted to examination on producing a certificate signed by three Fellows to the effect that he has been engaged in the Practice of Surgery for eight years, and is a fit and proper person to be admitted a Fellow.

Few consulting surgeons in England are without the Fellowship, and in most of the London hospitals appointments are unattainable without it.

##### APOTHECARIES' SOCIETY OF LONDON.

The Licence of the Worshipful Society of Apothecaries is perhaps the most useful medical diploma for the general practitioner in England. The monopoly enjoyed by this body for many years, in this respect, is not easily to be disturbed. The laws of many institutions require their medical officers to hold this diploma, and these laws are not readily altered. Though other medical qualifications are recognised by the Poor-law Board, there is no doubt that the guardians throughout the country—and they elect the medical officers—are familiar with the diploma of the Apothecaries' Society, and it is to them more of a guarantee than other qualifications of which they are ignorant. Everyone, therefore, who can show this certificate, intending to settle in *England* as a general practitioner—even if he take other diplomas—would probably consult his own interest by becoming a Licentiate of the Apothecaries' Society; and as the fee is only six guineas, a very large number of young men will, no doubt, secure this avenue to appointments.

In entering a School of Medicine, application is to be made to the Dean. In London the fees range from 80 to 100 guineas for the course of study required for the ordinary diplomas. The sum, if paid at once, is less than if paid in two or three instalments. From 40 to 50 guineas at the commencement of each of the two first years is an ordinary arrangement, the remainder being paid on entering the third winter. There is a tendency to slightly increase the fees in consequence of the improvements in schools and the additional requirements of the Examining Boards, but the amount does not differ sufficiently to make it of importance in the choice of a school.

#### NOTES ON THE HOSPITALS AND MEDICAL SCHOOLS IN LONDON;

CHIEFLY IN REFERENCE TO THE PRIZES, SCHOLARSHIPS, AND APPOINTMENTS OPEN TO STUDENTS.

##### ST. BARTHOLOMEW'S HOSPITAL.

H.R.H. THE PRINCE OF WALES is the President of this hospital, which receives within its walls upwards of 6,000 in-patients annually, and its out-patients and casualties amount to more than 144,000 annually. The staff at this ancient and popular institution is decidedly second to none. The Clinical Practice comprises a service of 710 beds, of which 322 are allotted to surgical cases, 227 to medical cases, 26 to diseases of the eye, 20 to diseases of women, and 81 to syphilitic diseases, while 34 are for convalescents at Highgate. Four house physicians and four house surgeons are appointed annually. The fee for these appointments is only nominal. The midwifery assistants, the ophthalmic house-surgeons, the clinical clerks, and the out-patient clerks and dressers are ap-

pointed, without fee, from among the diligent students. Sixteen free in-patient dresserships are awarded annually; other dresserships may be obtained on payment of the usual fees.

Accommodation is provided for residence of students in the college connected with the institution, for which an entrance fee of £2 2s. is required. By applying to the resident warden, Dr. Moore, students may obtain information respecting rooms in the college, or will be advised respecting residence out of the hospital.

In addition to the many valuable prizes and scholarships open to students at this institution, a new scholarship in science was founded last year of the value of £100, tenable for one year. The subjects for examination are Physics, Chemistry, Botany, and Zoology.

#### CHARING CROSS HOSPITAL.

This hospital, though at present one of the smaller ones, derives from its situation great advantages. It is in one of the most central positions in London, where there is constant communication with every part. When the present extensive alterations are completed 200 beds will be at the disposal of the staff, which, at the present time, reckons several names of eminence. In connection with it the practice of the Royal Westminster Ophthalmic Hospital, close by, containing 36 beds, affords an excellent opportunity for the study of that branch of the profession. Other special departments have been established, and the authorities have had the courage to establish them on a liberal basis, the hospital staff not monopolising them. The following scholarships are open to students: Two entrance scholarships, of the value of £30 and £20 respectively, tenable for one year, are awarded annually. Two scholarships are open for competition to matriculated students—the Llewellyn Scholarship of £25, for those who have just completed their second year; and the Golding Scholarship of £15, for those who have just completed their first year. The Governors' Clinical gold medal, and silver and bronze medals in all classes are awarded annually.

#### ST. GEORGE'S HOSPITAL.

One great advantage of this school is its unrivalled position, at the corner of Hyde Park, one of the most salubrious parts of the metropolis. Students can easily find lodgings within half an hour's pleasant walk. It is perhaps the most aristocratic of the London schools, and the present staff maintain their position as worthy successors of Hunter, Brodie, and other worthies who formerly taught in it. For some time past the authorities being aware of the insanitary state of the building, and the absolute need of improvement in which many portions of it stood, resolved to close its doors for about two months, and to have the interior arrangements remodelled after the present scientific method of conversion. This being satisfactorily attained, the hospital was reopened on the 9th inst. for the reception of patients, to the no small gratification of the governors and staff, who are to be congratulated upon their wisdom and energy in taking the initiative and carrying through so great an undertaking. Indeed, second year's students will hardly recognise its inner life when they re-enter on the 1st prox.

The hospital contains 350 beds—200 for surgical, and 150 for medical cases. There are special wards for diseases of the eye, diseases of women, &c. In addition to the ordinary curriculum, there are separate courses of lectures on ophthalmic, aural, dental, and orthopedic surgery, and on psychological medicine.

Upon payment of a compounding fee of 100 guineas, gentlemen may become perpetual pupils of the hospital. Perpetual pupils enjoy certain privileges in the matter of appointments, &c. The prizes, appointments, and scholarships open to students in this hospital are exceedingly numerous and valuable.

#### GUY'S HOSPITAL

This old favourite borough school still attracts the lion's share of students. It has long been one of the most popular in the metropolis, and still keeps up its renown. In special departments, Guy's is the most advanced. This hospital set the example of giving the appointments to its special departments to gentlemen not on the general staff.

Guy's is situated close to the London Bridge Railways, hence great facilities for getting to any part of London or the country. It is quite practicable for students to reside a little distance down either of the lines that converge at this point, and thus enjoy the benefit of country air during their hospital career. For those who wish to live close to the hospital, lodgings are to be had at a moderate price,

Every facility and encouragement is given to students to examine and study for themselves at the bedside, and they have opportunities of becoming clinical ward clerks to the physicians and surgeons, as well as dressers to the assistant-surgeons and dressers in the surgery. The house-physicians and house-surgeons are appointed directly by the treasurer. All the other appointments are made by the treasurer upon the recommendation of the Medical Council. Mr. Stocker will supply every information as to the many appointments, scholarships, and prizes open to students either before or after entrance.

#### KING'S COLLEGE.

This College gives instruction in all the faculties, and has a theological department. It was established by Church of England persons, in opposition to University College, which is a non-sectarian institution. King's, then, is the Church of England College. The College is situated close to Somerset House, in the Strand, having a frontage on the new Thames Embankment, within a few minutes' walk of several railway stations. A new wing, one storey high, in a similar style of architecture with Somerset House, and fronting the Thames Embankment, is being rapidly pushed forward, the dissecting-room and laboratory are being considerably enlarged, and new consulting-rooms and offices erected. The students' rooms are undergoing alteration and improvement, and a new and commodious drawing school is in course of construction. It is expected that the whole will be completed in time for the winter session. There is a junior school in connection with this college, to prepare boys to enter the college at a proper age. The hospital is only a short distance from the college, at the back of the Royal College of Surgeons, and although smaller than some of the London hospitals, the renown of its staff has always kept up its reputation, so that the King's is one of the most popular of the medical educational institutions in London.

#### THE LONDON HOSPITAL AND COLLEGE.

The Medical College of the London Hospital has been greatly enlarged, and is now very complete, lectures and demonstrations being given in all subjects required by the medical examining boards. In the new buildings the museum has been more than doubled in size, and a physiological and histological laboratory has been erected and amply furnished with microscopes and all needful appliances. Pathology is also systematically and practically taught in this school. The college, therefore, worthily supplements the great East-end hospital, which has long been famed as one of the finest fields of practical study. There are now a large number of scholarships and prizes of considerable value, but more important still to studious men, all the numerous appointments in the wards are open to pupils without extra payment, and it is almost impossible to exaggerate the value of the dresserships, clerkships, house-surgeons, house physicians, and other residential positions in a hospital of the first magnitude, where the staff take great interest in the development of its educational resources. A new wing will shortly be opened, raising the number of beds to 800.

#### ST. MARY'S HOSPITAL.

There is a medical school in connection with this hospital, which is located at Paddington, in close proximity to the Great Western Terminus. A Maternity Department is attached to the hospital. There are special departments for diseases of the eye, the ear, the skin, and the throat, in which clinical demonstrations are constantly given by the physicians and surgeons in charge of them. Students with slender purses will find the neighbourhood of the hospital a moderate one as regards lodgings, and easy of access by omnibus and the Underground Railway from all parts of London. Three resident medical officers are appointed for twelve months, and an obstetric officer for six months, who board free of expense in the hospital. A resident registrar is also appointed from amongst the students, with a salary of £100 a year. These appointments are awarded after competition, without additional fee. There are several scholarships, full particulars of which may be obtained of Dr. Shepherd.

#### MIDDLESEX HOSPITAL.

The school attached to this hospital is not a large one, but its pupils have passed the colleges in much greater proportion than some of the larger ones, thereby reflecting credit upon the staff attached. There is a special department for cancer cases, affording accommodation for thirty-three in-patients,

whose period of residence in the hospital is unlimited. Wards are also appropriated for the reception of cases of uterine disease and of syphilis, and beds are set apart for patients suffering from diseases of the eye.

Special attention is bestowed on the clinical instruction of the students both in the wards and out-patients' rooms. Three clinical prizes, including the governor's prize of twenty guineas, are annually awarded to those students who pass the most satisfactory examination at the bedside, and in the post-mortem room. Class prizes are given, and six resident clinical appointments are annually awarded after competitive examination, to students who have completed their education and complied with the regulations of the school. The officers thus appointed reside and board in the hospital free of expense.

#### ST. THOMAS'S HOSPITAL.

This magnificent building, or rather series of buildings, is situated at the foot of Westminster Bridge, on the south bank of the Thames, facing the Houses of Parliament. From its proximity to some of the largest factories in London, it affords scope for surgical practice from accidents second to none, whilst amongst the members of its staff are names of European reputation in medicine and science.

There is accommodation for residence and free maintenance in the college-house for the two house-surgeons, resident accoucheurs, one dresser, one obstetric clerk and assistant obstetric clerk, which appointments are awarded by competition. There are many prizes and scholarships.

The admission fee to practice and all the lectures is £40 for the first year, a similar sum for the second, £20 for the third, and £10 for each succeeding year, or £105 at one payment for unlimited attendance. Special entries may be made to any course of lectures or to the hospital practice; and a modified scale of fees is arranged for students entering in their second, third, or any subsequent year. Fee for general subjects required for students of dental surgery for two years, £45, or by instalments of £40 for the first year and £10 for the second year. All students have the opportunity afforded them of being engaged in the performance of practical duties in connection with the medical, surgical, obstetrical, ophthalmic, and pathological departments in the hospital. There is the Tite Scholarship, value £30 for three years. Three prizes for first year's students, at the end of both winter and summer sessions, of the aggregate value of £70, besides various medals and prizes open to students of any year.

#### WESTMINSTER HOSPITAL.

This is near the Abbey and the Houses of Parliament, upon one of the finest sites, and with convenience for locomotion and recreation equal to any other in the metropolis. It is well appointed in every respect, and one of the most moderate in respect to fees. It contains 191 beds, and received, during the past year, 1,802 in-patients and 19,422 out-patients. There are separate departments for diseases of the eye, diseases of the ear, diseases of the skin, diseases of the teeth, and diseases peculiar to women. In addition to the practice of the hospital, pupils who enter for the whole period of medical education are permitted to attend, without further fee, the practice of the Royal Westminster Ophthalmic Hospital, and that of the National Hospital for Paralysis. The whole course of study for the usual examinations may be here completed for £80, payable in two instalments. The perpetual fee is only eighty guineas, or £78 in one sum on entrance. Resident appointments, clerkships, and dresser-ships, are all conferred without extra payments. Suitable lodgings may be obtained in the neighbourhood, and at not more than a quarter of an hour's walk from the hospital. Some of the staff take pupils to reside with them.

#### UNIVERSITY COLLEGE AND HOSPITAL.

Few colleges in London have of late years been so successful as this, both in its annually increasing number of students and the number of them who subsequently pass their several colleges on first presentation. On its staff are names of considerable eminence, and from its central and healthy position everything is in its favour. The College, which is situated in Gower Street, about 100 yards from the hospital, gives instruction in every department of science, and specially prepares students for degrees in all the faculties at the University of London. There is, however, no theological faculty, the College, like the University with which it is in intimate connection, being founded on the non-sectarian principle. There

is also a faculty of science. University College School specially prepares boys to be ready at a proper age to enter the College. The scholarships and prizes open to Students in the Medical Faculty are probably as valuable as those attached to any other Medical School in the metropolis, Guy's and St. Bartholomew's excepted. There is the Surgical Fellowship, value £45 per annum for three years; the Physiological, value £70; Pathological Anatomy, £30; besides various other prizes and medals.

NOTE.—Where fuller information is required by the reader than that contained in the foregoing notes, it will generally be found on reference to our advertising columns, where also will be found the names of the staffs, lecturers, &c.

### DAYS AND HOURS OF THE INTRODUCTORY LECTURES

To be delivered at the different Metropolitan Schools.

Charing Cross Hospital—Dr. Douglas Powell—Oct. 1st, 4 p.m.  
St. George's Hospital—Dr. Dickinson—Oct. 1st, 4 p.m.  
Guy's Hospital—Sir Wm. Guil—Oct. 1st, 2 p.m.  
King's College—Prof. Ferriar—Oct. 1st, 4 p.m.  
London Hospital—Dr. Fenwick—Oct. 1st, 3 p.m.  
St. Mary's Hospital—Mr. Edmund Owen—Oct. 1st, 3.30 p.m.  
Middlesex Hospital—Mr. Andrew Clark—Oct. 1st, 3 p.m.  
St. Thomas's Hospital—Mr. MacCormac—Oct. 1st, 2 p.m.  
University College—Dr. Roberts—Oct. 1st, 3 p.m.  
Westminster Hospital—Dr. Potter—Oct. 1st, 8 p.m.  
Royal Veterinary College—Professor Tuson—Oct. 1st, 1 p.m.

### METROPOLITAN HOSPITALS TO WHICH NO MEDICAL SCHOOL IS ATTACHED,

The Practice being open to Students at the larger Hospitals.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—This is a large and important hospital at the East end, containing 164 beds. Consulting Physicians: Drs. T. B. Peacock, J. Risdon Bennett, E. Lloyd Rickett. Consulting Surgeon: Mr. John Hilton, F.R.S. Physicians: Drs. S. H. Ward, J. Andrew, J. C. Thorowgood, H. G. Sutton. Assistant-Physicians: Drs. A. Shepherd, Eustace Smith, W. H. Corfield, and J. B. Berkart.

EAST LONDON HOSPITAL FOR CHILDREN.—This institution, which contains 86 beds, has become quite inadequate to the requirements of the densely-populated district in which it is placed. Funds have been asked for, and largely subscribed for the erection of a more commodious building. Physicians: Drs. Barnes, Andrew Clark, J. M. Bruce, and Eustace Smith. Surgeons: Messrs. B. Shillitoe, A. Caesar, H. A. Reeves. House-Surgeons: Messrs. J. Magrath and J. Caesar. Secretary: Mr. Ashton Warner.

FEVER HOSPITAL, Islington.—260 beds. Physicians: Drs. Tweedie, Murchison, Broadbent, and Cayley. Consulting Surgeon: Mr. De Morgan.

GREAT NORTHERN HOSPITAL, Caledonian Road.—Physicians: Drs. Leared, Hardinge, Cholmeley, and Crucknell. Obstetric Physician: Dr. Gustavus C. P. Murray. Diseases of the Eye: Mr. B. J. Vernon. Surgeons: Messrs. Gay, W. Adams, T. Carr Jackson, and W. Spencer Watson. Aural Surgeon: Mr. Harvey. Dental Surgeon: Mr. C. J. Fox. Chloroformist: Mr. G. Eastes. House-Surgeon: Mr. A. Young.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—This is the largest institution for the treatment of affections of the chest in the United Kingdom, and contains 210 beds. Physicians: Drs. R. P. Cotton, K. Quain, J. E. Pollock, E. S. Thompson, C. T. Williams. Assistant-Physicians: Drs. R. D. Powell, J. Tatham, R. Thompson, Burney Yeo, F. Roberts. Three clinical assistants reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital. Terms, £8 8s. for three months; perpetual, £5 5s.

HOSPITAL FOR DISEASES OF THE THROAT, Golden Square, W.—This is the only institution in London for the special treatment of this class of disease. Consulting Physicians: Dr. Billing and Sir W. Jenner, Bart., M.D. Consulting Surgeon: Sir W. Ferguson, Bart. Physicians: Drs. Morell Mackenzie, Semple, and Prosser James. Surgeon: Mr. George Evans. Assistant-Surgeon: Mr. Pugin Thornton. Surgeon-Dentist: Mr. Oakley Coles.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, Queen Square, W.C., and Cromwell House, Highgate.—Students are admitted to the practice of this hospital, the staff of which consists of—Physicians: Drs. West and Dickinson. Assistant-Physicians:

**Drs. Gee, W. B. Cheadle, O. Sturges, A. L. Galabin, and R. J. Lee.** Surgeons: Mr. T. Smith, Mr. F. Howard Marsh, and Mr. J. W. Howard. Surgeon Dentist: Mr. T. Edgelow. Fee for three months' attendance, £3 8s.; perpetual, £5 5s. Secretary: S. Whitford. There are now 65 beds in the hospital, Great Ormond Street, and 52 beds at the country branch; total, 117.

**HOSPITAL FOR STONE,** Berners Street, close to the Middlesex Hospital.—The practice is open free to hospital students. Mr. W. J. Coulson, F.R.C.S., and Mr. W. F. Teevan, B.A., F.R.C.S., are the surgeons.

**HOSPITAL FOR WOMEN,** Endell Street, St. Giles's, W.C.—Consulting Physician: Dr. Priestley. Consulting Surgeon: Sir William Fergusson, Bart. Physicians: Drs. Haywood Smith, Arthur Edis, and Wiltshire. This institution receives women only as midwifery pupils.

**LONDON SCHOOL OF DENTAL SURGERY,** Leicester Square.—This institution has been removed since last year from its old and inconvenient quarters in Soho to a much more commodious and attractive edifice. The meetings of the Odontological Society are also held here. In winter lectures are delivered on Mechanical Dentistry by Mr. J. S. Turner, on Wednesdays, at seven p.m.; on Metallurgy in Dentistry, by Mr. G. H. Makins, on Tuesdays and Fridays, at 6.30 p.m. In summer Mr. S. H. Cartwright lectures on Dental Surgery and Pathology, and Mr. C. S. Tomes on Dental Anatomy and Physiology. General fee for special lectures required for the curriculum, £15 15s. Fee for two years' practice at the Dental Hospital in connection with the above required by the curriculum, £15 15s.

**PHARMACEUTICAL SOCIETY OF GREAT BRITAIN,** Bloomsbury Square, London.—**SCHOOL OF PHARMACY.**—The session commences October 1st, and extends to the end of July. Lectures on Chemistry and Pharmacy will be delivered by Professor Redwood on Monday, Tuesday, and Wednesday, at nine a.m. Also lectures on Botany and Materia Medica, by Professor Bentley. On Friday and Saturday, at nine a.m., an additional course of Systematic and Practical Botany will be delivered at the Royal Botanic Gardens, Regent's Park, on Friday and Saturday, at nine a.m., commencing in May and ending in July. The Laboratory, under the direction of Professor Atfield, will be open from ten a.m. to five p.m. daily, excepting Saturdays, when it will be open from ten a.m. to two p.m. Students may enter at any period during the session.

**ROYAL FREE HOSPITAL,** Gray's Inn Road.—This hospital contains 102 beds. Of the smaller metropolitan hospitals few offer a more extensive field for students in medicine and surgery. Physicians: Dr. O'Connor, Dr. Cockle, and Dr. Rickards. Surgeons: Mr. Victor De Meric, Mr. Frederick Gant, Mr. John D. Hill. Secretary: Mr. J. S. Blyth, from whom full particulars of the dressships and clerkships may be obtained.

**ROYAL HOSPITAL FOR DISEASES OF THE CHEST,** City Road, E.C.—This hospital, although it treats nearly 6,000 out-patients annually, is at present only able to receive 12 in-patients. A new building is in contemplation, which will raise the number of beds to over 60. Consulting Physician: Herbert Davis. Physicians: Drs. Dobell, H. H. Crucknell, G. Goddard Rogers, and P. J. Hensley. Consulting Surgeon: Mr. J. Adams. Surgeon: Mr. Alfred Cooper. Resident Medical Officer: Mr. Henry Harris.

**ROYAL LONDON OPHTHALMIC HOSPITAL,** Bloomfield Street, Moorfields, E.C.—Founded 1804. 70 beds. Consulting Physician: Dr. F. J. Farre. Consulting Surgeon: Mr. J. Dixon. Surgeons: Messrs. Critchett, Bowman, Wordsworth, Streathfield, J. W. Hulke, G. Lawson, J. Hutchinson, J. Couper, and J. Soelberg Wells. House-Surgeon: Mr. Baller. Number of patients annually, about 20,000.

**ROYAL VETERINARY COLLEGE.**—Lectures, Clinical and Pathological Demonstrations, and General Instruction, are given on the Pathology of the Horse and other domesticated animals, including Epizootics, Parasites, and Parasitic Diseases; also on Anatomy, Physiology, Histology, Chemistry (General and Practical), Materia Medica, Toxicology, Botany, Therapeutics, and Pharmacy, Hospital Practice, Obstetrics, Operative Surgery, the Principles and Practice of Shoeing, &c. Students are required to attend one summer and two winter sessions at least before being eligible for the examination for the diploma of the Royal College of Veterinary Surgeons. Professor Simonds is the Principal.

**ROYAL WESTMINSTER OPHTHALMIC HOSPITAL,** King William Street, Charing Cross.—The hospital contains 36 beds, and the patients (10,000 annually) are seen and operations performed daily at one. The days of attendance of the surgical staff are Monday and Friday, Mr. Power and Mr. Rouse. Tuesday, Thursday, and Saturday, Mr. Hogg. Wednesday and Saturday, Mr. Cowell. The practice of the hospital is open to students. Fees, for six months, £3 8s.; perpetual, £5 5s. Students of the hospital are eligible for the post of House-Surgeon.

**SOUTH LONDON SCHOOL OF CHEMISTRY AND PHARMACY,** 325 Kennington Road, S.E.—Director, Dr. Muter. Lectures are delivered daily, at various hours, from nine till five, and the

laboratory is open for practical chemistry from ten till four. Special instruction in food analysis is given daily at the Public Laboratory, Kennington Cross.

**VICTORIA HOSPITAL FOR CHILDREN,** Queen's Road, Chelsea.—The hospital contains 50 beds, and has a large out-patient department. The practice is open daily at twelve. Fees, for six months, £3 8s.; perpetual, £5 5s. Physicians: Drs. Evans and Cavafy. Assistant-Physicians: Drs. Jones, Grigg, and Laking. Surgeon: Mr. Cowell. Assistant-Surgeons: Mr. F. Churchill and Mr. Roberts. Dental-Surgeon: Mr. Risdon. House-Surgeon and Pathologist: Mr. Peregrine.

**WEST LONDON HOSPITAL,** Hammersmith Road, W.—A well-appointed hospital, containing 68 beds. In-patients, 407. Out-patients, 20,240. Consulting Physician: Dr. Mandesley. Consulting Physician-Accoucheur: Dr. W. O. Priestly. Consulting Surgeons: Mr. S. A. Lane, Mr. William Bird. Physicians: Dr. Goddard Rogers, Dr. Thorowgood. Physician for Diseases of Women: Dr. Wiltshire. Surgeons: Mr. W. F. Teevan, Mr. Alfred Cooper. Surgeon for Diseases of the Eye: Mr. B. J. Vernon. Junior Physicians: Dr. Fish, Dr. Fothergill. Junior Surgeons: Mr. J. A. Bloxam, Mr. H. T. Butlin. Surgeon-Dentist: Mr. H. E. Sewill. Analytical Chemist: Mr. William Crookes, F.R.S. Resident Medical Officers: Two House-Surgeons, Apothecary. The practice of this hospital is open to all students and members of the medical profession. Gentlemen desirous of acting as clinical clerks or dressers can obtain all information by application to Mr. T. Alexander, at the hospital.

## ENGLISH PROVINCIAL MEDICAL SCHOOLS.

### BIRMINGHAM QUEEN'S COLLEGE.

THE Practices of the Queen's and general hospitals have been amalgamated for the purpose of Clinical Instruction under the direction of the Birmingham Clinical Board, by whose order all schedules are signed and all examinations conducted. The hospitals have a total of upwards of 400 beds. 4,500 in-patients and 45,000 out-patients are treated annually. Birmingham has the character of providing the most varied clinical instruction and practical operative surgery of all the provincial schools. Its staff is certainly of a very high order.

Practical Pharmacy is also taught in the dispensaries of the hospitals.

**Appointments.**—At the General Hospital—Resident Medical Assistant, Resident Surgical Assistant, two Resident Dressers, tenable for six months. At the Queen's Hospital—Resident Medical Assistant, Resident Surgical Assistant, Resident Obstetric Assistant, tenable for six months.

**Clinical Prizes.**—The following Prizes are given annually:—Senior Medical Prize, for Third and Fourth Year Students, First Prize, £6 6s., Second Prize, £4 4s.; Senior Surgical Prize, for Third and Fourth Year Students, First Prize, £6 6s., Second Prize, £4 4s.; Junior Medical Prize, for Second Year Students, First Prize, £5 5s., Second Prize, £3 3s.; Junior Surgical Prize, for Second Year Students, First Prize, £5 5s., Second Prize, £3 3s.; Midwifery Prize, £4 4s. The Examinations for all the Appointments and Prizes are conducted by the Clinical Board, and are open for competition to all students registered by the Clinical Board.

Fees for attendance for four years on the Medical and Surgical Practice, and on the Clinical Lectures at both Hospitals, £31 10s. One year's attendance, £15 15s.; six months' attendance, £10 10s.; special department, for Midwifery and Diseases of Women (optional), £2 2s.

**BRISTOL SCHOOL OF MEDICINE.**—The Bristol General Hospital attached to the School, in which there is ample scope for practice, contains 154 beds. The number of out-patients treated last year was over 13,000. The staff of lecturers is as follows:—Medicine, Drs. S. Martyn and W. H. Spencer. Surgery and Surgical Anatomy, Messrs. R. W. Ooe, R. W. Tibbits, E. C. Board, N. C. Dobson, H. M. Chute, A. E. A. Lawrence, and Hy. Waldo. Materia Medica is taught by Dr. G. F. Burder. Physiology by Messrs. G. F. Atchley and R. S. Smith. Midwifery by Dr. J. G. Swayne. Chemistry by Mr. Coomber.

Competitive Examinations are held amongst Students of the First, Second, and Third Years respectively, and Prizes of Money, Instruments, and Books are awarded annually.

The Certificates of this School are accepted by all the Examining Boards.

The General Perpetual Fee is 55 guineas.

Medical and Surgical Hospital Practice and Clinical Lectures are attended at the Royal Infirmary or at the General Hospital, at which institutions additional Prizes and Scholarships are annually offered for competition amongst the students. Arrangements are in progress for the establishment in Bristol of a College of Science and Literature, of which the existing Medical School will form a department.

**LEEDS SCHOOL OF MEDICINE.**—*Lecturers in the School:* Anatomy, Robert T. Land, M.D., John A. Nunneley, M.B., and E. Robinson. Physiology, C. J. Wright and John Horsfall, F.R.C.S. Medicine, John D. Heaton, M.D., F.R.C.P., T. C. Allbutt, M.A., M.D. Pathology, R. P. Oglesby. Surgery (including the Practical Course), Claudius G. Wheelhouse, F.R.C.S., T. Fridgin Teale, M.A., F.R.C.S., T. R. Jessop, F.R.C.S. Mental Diseases, J. Crichton Browne, M.D., F.R.S.E. Chemistry, T. Fairley, F.C.S. Materia Medica, John E. Eddison, M.D. Midwifery, W. Hall. Forensic Medicine, Thomas Scattergood. Botany, Edward Atkinson. Comparative Anatomy, T. C. Allbutt, M.A., M.D., and E. Atkinson. Demonstrations of Anatomy, R. P. Oglesby, Edmund Robinson, and A. F. McGill.

Clinical Lectures are given by the Physicians and Surgeons to the Infirmary.

Ophthalmoscopic Demonstrations and Demonstrations of Skin Diseases are given in the Infirmary by the Surgeons in each department.

Besides the Infirmary, there is a large Dispensary and a Fever Hospital, both of which are open to Students of the School.

**West Riding Lunatic Asylum, Wakefield.**—Dr. J. Crichton Browne, F.R.S.E., the Medical Director of the West Riding Lunatic Asylum, lectures on Mental Diseases during the Summer Session. The Systematic Lectures are given at the School, and the Clinical Lectures at the Asylum, which now accommodates 1,500 patients.

Special Prizes of the value of £10 each are given in the classes of Clinical Medicine, Clinical Surgery, and Forensic Medicine. Silver and Bronze Medals and Books are given in the Class Examinations.

Composition Fee, entitling to attendance upon all the required Courses of School Lectures, 44 guineas. The fees for attendance upon the Medical and Surgical Practice of the Hospital are 20 guineas each for three years, and proportionally less for single sessions. The fee for the Comparative Anatomy Course is not included in the Composition Fee.

**LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.**—Four Exhibitions, value £31 10s. each, consisting of free board and residence in the Royal Infirmary for six months, with dresserships, on award of the Medical Board. Six Dressers and Six Clinical Clerks are elected quarterly. Pupils of the Infirmary are admitted to learn Pharmacy in the dispensing department for six months.

*Fees.*—For six months' medical practice, 5 guineas; twelve months', 6 guineas. Surgical, 6 guineas for six months; 8 guineas for twelve months (this includes admission to the Practice of the Lock Hospital adjoining the Infirmary). Perpetual Medical and Surgical Practice, 32 guineas.

The hospital contains 300 beds, including wards, with 40 beds for the treatment of diseases of women.

**MANCHESTER—OWENS COLLEGE SCHOOL OF MEDICINE.**—This school, as most of our readers are aware, has resulted from the amalgamation of the Manchester Royal Infirmary School of Medicine with the Owens College, and occupies in the provinces a somewhat similar position to that of University College and Hospital in London. It has a Faculty of Science as well as of Medicine, with departments of Laws and Arts. Since the amalgamation a new Medical School has been built, on the most approved principles, at the western extremity of the College estate. On the ground floor are two large lecture theatres, a library, and a museum. Over the lecture theatres is a dissecting-room, and over the library a physiological laboratory.

The course of instruction afforded to students is most complete. Three of the most important chairs, those of anatomy, physiology, and chemistry, are held by professors who almost entirely devote their time to the work of instruction.

Students who may wish to engage in physiological or pathological researches will find opportunities for study in the complete and well-furnished physiological laboratory. Two valuable physiological scholarships are placed for competition in this branch as an incentive to original research.

*Fees.*—A Composition Fee, which may be paid in one sum of £48, or in two sums of £25 each at the commencement of the first and second years of studentship, admits to the whole of the Lectures required to qualify for the Examinations for Medical Degrees in the University of London, the Diplomas of the Royal College of Physicians, the Fellowship and Membership of the Royal College of Surgeons, and the Licence of the Apothecaries' Society.

The following is the staff of the College Medical Department:—

*Principal of the College.*—J. G. Greenwood, B.A.

*Director of Medical Studies.*—Professor Southam, F.R.C.S.

*Lecturers.*—General Anatomy and Physiology, William Smith, F.R.C.S. Practical Physiology and Histology, Arthur Gamgee, M.D., F.R.S. Practical Anatomy, J. B. Perrin, M.R.C.S. Comparative Anatomy, W. C. Williamson, F.R.S. Chemistry, Henry E. Roscoe, B.A., F.R.S., and C. Schorlemmer, F.R.S. Medicine, William Roberts, M.D., F.R.C.P., and J. E. Morgan, M.D., M.A. (Oxon.) Surgery, George Southam, F.R.C.S., and Edward Lund, F.R.C.S. General Pathology and Morbid Anatomy, Henry Simpson, M.D., and Julius Dreschfeld, M.D. Midwifery and Diseases of Women and Children, John Thorburn, M.D. Materia Medica and Therapeutics, Alexander Somers, M.R.C.S., and Daniel John Leech, M.B. (Lond.) Forensic Medicine, G. Morley Harrison, M.R.C.S. Ophthalmology, Thomas Windsor, M.R.C.S. Botany, Professor W. C. Williamson, F.R.S. Hygiene and Public Health, Arthur Ransome, M.D., M.A. (Cantab.)

**NEWCASTLE-ON-TYNE COLLEGE OF MEDICINE.**—The medical school here is not of a very extensive character, nor are its students numerous; still, for some of our readers it may be convenient to send their sons and we therefore give the following particulars:—

Hospital Practice is obtained at the Newcastle Infirmary, which has 230 beds, and in which the required Clinical Lectures are delivered. Number of patients last year, 16,696.

Four Resident Dressers are chosen from the senior students every six months. Fee, £10. Composition Fee to all the Lectures, 50 guineas.

*Medical Scholarships in the University.*—Four Scholarships of £25 a year, each tenable for four years by students residing in Durham or Newcastle, and not of sufficient standing to proceed to a Licence in Medicine.

**SHEFFIELD SCHOOL OF MEDICINE.**—Students at this College obtain excellent instructions in Medical and Surgical Practice at the General Infirmary, which contains 200 beds, and is provided with a Museum and Pathological and Post-Mortem Theatres.

The Fees for perpetual attendance are £15 15s. for Medical, and £21 for Surgical Practice; for 12 months' Medical and Surgical Practice, each £10 10s.; and for 6 months', £6 6s. each.

There is also the Sheffield Hospital and Dispensary, containing 99 beds, and the Hospital for Diseases of Women, to which students are admitted.

The Perpetual Fee for attendance on all the Lectures required by the Royal College of Surgeons and the Apothecaries' Hall is £42.

Prizes to the value of £30 and certificates of honour are given annually.

Some of the lecturers, and other local members of the profession, receive house pupils, which will be found far preferable to life in ordinary lodgings.

*NOTE.*—Our advertisement columns, of which an Index will be found at end, will in most of the above cases supply further information if required.

MR. MURRAY, B.A., Arkteon House, Wray Crescent, TOLLINGTON PARK, N., prepares gentlemen for the Preliminary Examinations at the Royal College of Surgeons and Apothecaries' Hall, and the Matriculation at the University of London.

## DAYS AND HOURS OF THE INTRODUCTORY LECTURES

*To be delivered at the different Provincial Schools.*

Durham University—Mr. J. Russel—Oct. 1st, 2 p.m.  
Queen's College, Birmingham—Dr. Alfred Hill—Oct. 1st, 3 p.m.  
Leeds School of Medicine—Mr. C. G. Wheelhouse—Oct. 1st, 4 p.m.  
Liverpool School of Medicine—Mr. Walker—Oct. 1st, 3 p.m.  
Manchester, Owen's College—Professor Huxley, F.R.S.—Oct. 2nd.  
Sheffield School of Medicine—Dr. J. C. Hall—Oct. 1st, 4 p.m.

## MEDICAL EDUCATION IN IRELAND.

## THE CAREER OF THE IRISH STUDENT.

The practice of the profession in Ireland, though not nearly as remunerative as in England, still affords a certain prospect to any medical man who is content with modest independence. Irish medical men pride themselves on holding a higher social position than the English general medical practitioner. They are entitled to meet the gentlemen of their locality on terms of equality, and it is not necessary or usual for them to endanger their prestige by the adoption of the trading or Christmas bill system which obtains elsewhere. In fact, what they lose in income they gain in rank.

In order to put the career of the Irish student as plainly as possible, we narrate the progress of an ideal person, from the day on which he takes his first step towards medicine to the hour of his issue from the cocoon of his studentship a fully-developed surgeon.

The parents and guardians of Master Robert Sawyer have, after much discussion, decided that he shall be a doctor. He has had a moderate amount of schooling, at least the very moderate amount which is essential for the medical preliminary examination, and his father is ready to expend about £130 on his medical education, that sum being divided over four years, or paid down in order to secure the advantage of a considerable saving.

## THE CHOICE OF UNIVERSITIES AND COLLEGES

will depend on various circumstances, and on the aspirations of Master Sawyer. If he is intended to make a fortune and enlighten his generation as a metropolitan practitioner, and if money and education are plenty, he will probably take University degrees in arts and in his profession. If the attainment of good professional rank on moderate terms be desired, the College of Surgeons and College of Physicians will serve every purpose. For University degrees it is to be remembered the student must undertake the prolonged study of classics and science in addition to his medical, surgical, and anatomical studies, and he will have to pay a considerable sum for this course of teaching, and, in the case of the Queen's University, to live for a certain period at the college where he studies. But if he is content to face the expense and labour he will enter the profession with all the prestige of an educated gentleman. In fact, the question whether he will or will not lay out for himself a University graduation in arts and medicine depends principally on whether he has money and time to give to it, and whether or not he means to practise in the metropolis. The Queen's University places at the disposal of the student a cheap University degree, and thereby attracts many applicants, but it is burdened by the necessity for the residence of the student for a time

at Galway, Cork, or Belfast, and, in the question of prestige, can hardly pretend to compete with the time-revered University of Dublin.

The Colleges of Surgeons and Physicians of Ireland confer qualifications which may stand well beside any in the United Kingdom, and as they do not require either residence or anything more than a single arts examination, they continue to be the licensing bodies for the rank and file of the profession in Ireland. If a student contemplates provincial practice—the army or navy—or a dispensary, he will most probably take the usual licences from the two Colleges. If he contemplates the lowly function of a country apothecary he *must* take the licence of the Dublin Apothecaries' Hall, which is in law equivalent to a medical degree. If he hopes to achieve a considerable private practice he will find it necessary to obtain other medical and surgical degrees.

## THE CHOICE OF SCHOOLS.

It must not be supposed that a student who intends taking a degree or diploma in any college must take his lectures in the school attached to that college, if there be one. On the contrary, with few exceptions, all certificates of attendance on lectures are interchangeable, and a student, no matter what medical school he may have studied in, will be admitted to any university or college. To this rule there is an exception. The Queen's University insists on certain courses being attended in one of the Queen's Colleges.

There is in some cases a sort of semi-official connection between certain colleges and hospitals, as between Trinity College and Sir Patrick Dun's, between the College of Surgeons and City of Dublin Hospital, and between the Catholic University and Mater Misericordiae Hospital; but this connection only exists because the professors of the college are in many instances officers of the hospital, and it confers no special immunity or privilege on the student of such hospital.

The choice of a school, hospital, or college having been made, Master—now *Mister*—Sawyer is perhaps sent to these to pass his

## PRELIMINARY EXAMINATION

in general education, but if he be either lazy or ignorant, he may adjourn that unpleasant process, *de die in diem*, until the eve of his final qualification as a surgeon, when, if he does so, he will find himself in possession of a mental muddle of Latin and physic. The preliminary examination is, however, not to be feared.

We strenuously advise the parents of the student to insist on his passing his preliminary education before he enters a medical school or hospital, and thus the student will relieve his mind of the apprehension of a future examination, which he will assuredly put off to the last moment if he can.

The preliminary examination (of the subject of which details will be found in the official regulations of each college) having been passed or postponed, Mr. Sawyer comes to town to begin work.

He may do so either (1) on his own account, or (2) he may become voluntarily a pupil of some medical man, usually a teacher or hospital surgeon, who can assist him in his studential course. This is by no means a require-

ment of any of the colleges; it is purely a matter of option. Should the student pursue the first course, he usually comes to town, takes a lodging close to his school and hospital, either by himself or in companionship with some *chum*, and either arranges to maintain himself or to board with his landlady. There is, of course, every degree of expense and comfort, but we should say that reasonable yet frugal living may be had in Dublin at about 10s. per week for lodging, and £5 to £6 per month for maintenance.

We would here, as a matter of private judgment, remark that it is better for parents to have board provided on a good substantial scale by the house. Young men are too apt to spend their money on luxuries or extravagancies, and make up the deficit by using insufficient food, to the great injury of the health.

#### COST OF EDUCATION.

Should the student proceed on his account, the lectures necessary for the L.R.C.S.I. will amount to £65; hospital attendance about £25; lying-in hospital from £4 4s. to £7 7s. These, with the diploma fee of £26 5s., represent the essentials. The sum of £50, paid down at the commencement is taken by the College of Surgeons as payment in full for all lectures requisite, and all the hospitals allow a considerable discount. Thus, the absolute payment will amount to somewhere about £83, taking the minimum mode of payment. In addition to this sum are to be considered the payments for "grinding," or "coaching," as the Londoners call it, a process by no means necessary to any industriously inclined student, particularly under the new and more practical *régime*, where "tips" will be less useful than the practical knowledge and the fall of the mere coached be rendered probable by being asked to put his ideas on paper, examine his patient, make his diagnosis, and order his prescription. The fixed sum is at present, for private teaching, £15 15s. for the surgical and medical qualifications, and £5 5s. for pharmacy, &c. Should the candidate "grind" for the army and navy examinations, a fee varying from £10 10s. to £21 is, we believe, usual. Should the candidate perform operations on the subject as a practice, they will cost something extra. So that, assuming the extras or voluntary costs are incurred, the total will vary, say, from £114 to £120 on a moderate scale: it is, of course, to be expected that pupil holders should have some extra payment; we therefore might name for them 140 guineas.

#### PAYMENT OF FEES.

If Mr. Sawyer becomes an apprentice, he need trouble himself nothing about his payments. If he is his own manager, he must enter his name with the secretaries of the school and hospital, and pay for the lectures and hospital he intends to take out. If he is wise he will not adjourn the majority of his lectures, as he may, to the next year, but will take in his first year a full third of his curriculum. He is supposed to pay the professor's fee or hospital fee in full on entering his name, but few students do so, and many, we are sorry to say, are in the habit of entering for the minimum allowable number of lectures, and paying the minimum allowable proportion of the fee, putting off the attendance perhaps for ever, certainly until the last moment, and adjourning the payment until they take up the certificates.

By a most objectionable laxity of system a student may

get credit for one of his four years of his attendance by paying a couple of guineas for dissections, and he may think himself safe in doing so if money be scarce; but if he does not pay his full third or fourth of the fees each year it often happens that he has to put off his examination from year to year—perhaps for ever—for want of the money to pay the accumulated fees of previous years.

The entry of names and commencement of study is supposed to date from the 1st of October in each year, but really does date from the 1st of November, and may be delayed by the dilatory until the 25th of the same month.

Mr. Sawyer then begins work, attending hospital each morning at nine o'clock, and occupying his day from half-past eleven to five between lectures and dissections. His holidays—if the term be not ignoble—are a fortnight at Christmas and a week at Easter, and he finally returns home at the end of July.

The progress of each year is the same, except that he usually devotes more attention to "grinding," dissection, and hospital dressings, and less to lectures in his later years of study, and after the expiration of his third session, his student life, whether it begin in laziness and end in hurry and incompetency, or whether it commence in diligence and end in the confidence of proficiency, ends with the last examination, and he goes forth into the world either an ignoramus or a reliable surgeon, whichever his choice may have been.

#### PRIVATE TEACHING, OR "GRINDING."

THE classes for private instruction, or "grinding," as it is technically and generally called, are carried on in Dublin with universality and success.

As a rule, all private teachers are connected with schools of medicine, and are in every respect highly qualified, many of them being also hospital physicians or surgeons, and therefore in a position to afford the special advantages in the way of clinical instruction to their pupils.

Grinding is followed in two methods—namely, on what are commonly known as the "public" and the "private" plans. In the former, a number of gentlemen, varying in different schools from two to four, associate themselves into a firm, or co-partnership, and each man, selecting particular branches, gives instruction to those only. For these classes a pupil may enter at any period of his course, by payment of a certain sum; but as the amount demanded generally is the same at whatever period of his course the student joins the class, and as he is taught for it until he obtains his degrees, it is usual to enter as early as possible, so as to secure the largest amount of instruction; but while there can be no objection to entering the name at the earliest period, we strenuously advise the student not to devote himself to "the grind" for the first, or even for his second year of study, but to apply himself to his hospital and dissecting.

As an example of the method pursued with regard to these "public grinds," we cannot do better than give the following extract, treating on the subject, from the book of instructions and information for students issued by the Professors of the School of Surgery of the Royal College of Surgeons:—

"In these classes students are taught so as to ensure that the subject shall be thoroughly understood by them.

"They are divided into senior and junior, according to the year of study, capacity, and diligence of the pupil.

"The subjects are—

"Practice of Medicine, Midwifery, and Surgery.

"Anatomy and Physiology.

"Materia Medica, Botany, and Chemistry.

"At least four classes are held daily (besides those for junior) at such times as do not interfere with the lectures at the School, each lasting for one hour—part of these classes being in the evening, for those who cannot otherwise attend. The fee is £18 18s., half of which is paid at the time of entry, the remainder when the diploma or degree is obtained.

"Should *Materia Medica*, Botany, and Chemistry not be required, £15 15s. for all the other classes divided in a similar manner.

"The fee for *Materia Medica* alone is £5 5s.

"For those who have already obtained professional qualifications, there are classes held for the army and navy medical competitive examinations, when special instruction is given in all the subjects required. Fee for these classes varies from £10 10s. upwards, according to the length of time required."

"Private grinding" is simply an arrangement quite independent of the other. A student who may, or may not, be a member of another class wishes for instruction; he goes to a "grinder," who, for a sum of, usually, £3 3s. per month, instructs him in the required branches of his profession. As a rule, each teacher devotes himself to particular subjects: thus, one gentleman grinds in, perhaps, Anatomy, Physiology, Surgery, and Medicine, another in Surgery alone, whilst a third will teach Chemistry, Botany, and *Materia Medica*.

In some schools slight differences of system are obtained: thus, a pupil may enter for the subjects he requires by paying a fixed sum, which entitles him to attend for the length of a session, but gives him no further claim on the attention of his grinder.

Each of these plans will be perceived to have its own particular advantages. By entering for public grinding a pupil, on the payment of a moderate sum, secures that he shall be taught all his necessary subjects; while, on the other hand, if he enters for private grinding, he may, from being in a smaller class, secure a larger amount of individual attention; but does so at an increased expense, and must pay separately for the various branches of his teaching.

It does not require a very arithmetical head to see the difference between paying—say £15 15s. for being taught for four years at least, in Anatomy, Physiology, Medicine, and Surgery, and paying £3 3s. per month for instruction in Anatomy and Physiology, and the same for Surgery or Medicine.

A list of the private teachers will be found in another part of our issue.

## REGULATIONS AND BYE-LAWS OF LICENSING BODIES IN IRELAND.

### UNIVERSITY OF DUBLIN.

(For Names of Professors and Examiners see Advertisement.)

#### REGULATIONS OF THE SCHOOL OF PHYSIC.

##### *Matriculation.*

Every student must be matriculated by the senior lecturer, for which a fee of five shillings is payable; but he need not attend any of the Arts Courses unless he desire to obtain a Licence or Degree in Medicine or Surgery. No student can be admitted for the Winter Courses after the 25th November.

#### QUALIFICATIONS FOR DEGREES AND LICENCES.

##### *Bachelor in Medicine.*

Candidates must be graduates in Arts, and may obtain the degrees at the same commencements as the B.A., or at any subsequent one. The medical education of a Bachelor in Medicine is of four years' duration, and comprises the following lectures:—

*Winter Courses.*—Anatomy and Physiology; Practical Anatomy, with Dissections; Surgery; Chemistry; Practice of Medicine; Midwifery.

*Summer Courses.*—Botany; *Materia Medica* and Pharmacy; Institutes of Medicine; Medical Jurisprudence and Comparative Anatomy; Heat; Electricity and Magnetism.

Hospital attendance on a Medico-Chirurgical Hospital during three courses of nine months each, with clinical lectures; six months' Practical Midwifery. Six months' Dissections and three months' Laboratory instruction in Chemistry are required.

The Courses may be attended at any recognised Medical School.

The fee for the *Licent ad Examinandum* is £5.

The fee for the degree of M.B. is £11.

##### *Doctor in Medicine.*

A Doctor in Medicine must be M.B., or qualified to take that degree, for three years. He must also read two Theses before the Regius Professor of Physic.

Total fees for this degree, £13.

##### *Bachelor in Surgery*

Must be a B.A., and have spent four years in the study of Surgery and Anatomy. (a)

The Curriculum comprises the following, in addition to the Course for the M.B.:—

Theoretical and Operative Surgery ...	One Course.
Dissections ... ..	Two Courses.
Ophthalmic Surgery ... ..	One Course.

Nine months in a metropolitan hospital.

Candidates are required to perform operations on the dead subject.

Candidates for the B.S. who have already passed the M.B. will be examined in Anatomy and Surgery only.

Fee for the *Licent ad Examinandum*, £5.

Fee for the degree of Bachelor in Surgery, £1.

##### *Master in Surgery*

Must be a B.S. of three years' standing, and must read two Theses, as for the M.D.

Fee for the Degree of Master in Surgery, £11.

#### UNIVERSITY LICENCES.

Candidates for the Licences in Medicine or Surgery must be matriculated in Medicine, and must have completed two years in Arts.

##### *Licentiate in Medicine.*

The Course and Examination are the same as for the M.B. An L.M., on proceeding to the degree of B.A., may become a B.M. on paying the fees without further examination.

Fee for the *Licent ad Examinandum*, £5.

Fee for the Licence in Medicine, £5.

##### *Licentiate in Surgery.*

The Course and Examination necessary for the Licence in Surgery is the same as for the degree of Bachelor in Surgery

Fee for the *Licent ad Examinandum*, £5.

Fee for the Licence in Surgery, £5.

#### MEDICAL SCHOLARSHIPS.

Two Medical Scholarships are given annually, value £20 per annum each, tenable for two years, the examinations for which are held each year in June, in the following subjects:—Anatomy and Physiology, Chemistry, *Materia Medica*, Botany, Experimental Physics, and Comparative Anatomy.

##### *Medical School Exhibitions.*

The Professors of the University School give three Exhibitions annually, two senior, value £15 and £10, open to all students who have been three years attending the school, the subjects being—Practice of Medicine, Surgery, Pathology, and Forensic Medicine; one junior, value £15, the time and subjects of examination being the same as those for the Medical Scholarship.

The Board of Trinity College have recently passed orders:—  
1. That three-fourths of the lectures must be attended.  
2. That a daily roll be called by each Professor.

Students entering for Demonstrations and Dissections are required to pay Eight Guineas before December; Dissections only, Five Guineas; Demonstrations only, Three Guineas.

Candidates for the M.B. are required to produce a certificate of actual attendance upon cases of Fever.

(a) Students in the School of Physic before 22nd June, 1872, may obtain the M.Ch. according to the Regulations previously in force.

(Full particulars as to the Educational Staff, Hours of Lectures, &c., in the School of Physic of the University will be found in our advertising columns.)

Official regulations may be obtained from the Rev. S. Haughton, F.T.C.D., Trinity College, Dublin.

## THE QUEEN'S UNIVERSITY IN IRELAND. FACULTY OF MEDICINE.

### DEGREE OF DOCTOR OF MEDICINE.

EACH candidate for the degree is required—

1. To have passed in one of the Queen's Colleges the examination for Matriculation in Arts. 2. To have attended in one of the Queen's Colleges lectures on one Continental Language for six months, and on Natural Philosophy for six months; also two Medical Courses. For the remainder of the medical courses, certificates will be received from any recognised lecturer. 3. To pass three University Examinations.

The Medical Curriculum is divided into two periods of two years each.

The first period comprises attendance on Chemistry, Natural History, Anatomy and Physiology, Practical Anatomy, and Materia Medica, Practical Chemistry in a recognised laboratory, and six months of a medico-chirurgical hospital.

The second period comprises Anatomy and Physiology, Practical Anatomy, Surgery, Midwifery and Diseases of Women and Children, Medicine, Medical Jurisprudence, Practical Midwifery, and eighteen months' Hospital Practice.

At least two of the above courses of lectures must be attended in some one of the Queen's Colleges.

The University Examinations are held twice in each year, in June and September.

Each candidate for examination must forward to the Secretary, before the 1st of the month, notice of his intention to offer himself, along with his certificates.

### THE FIRST UNIVERSITY EXAMINATION IN MEDICINE

Comprises a modern language, Experimental Physics, Zoology, and Botany.

Students may present themselves at any time after the close of the first winter session. Before being admitted to examination each candidate must produce evidence of having completed the prescribed courses.

### THE SECOND UNIVERSITY EXAMINATION IN MEDICINE

Comprises the following subjects: Anatomy, Physiology, Materia Medica, and Chemistry, to which will be added Zoology and Botany in the examination of candidates who have not previously passed the first examination. Such candidates may either undergo their examination in Modern Languages and Experimental Physics as a part of the second examination, or at any time between the second and the degree examination.

Students may present themselves for the second examination at the termination of the first period of the curriculum, or at any subsequent period, but no student can postpone his second examination until he presents himself for his degree examination.

### DEGREE EXAMINATIONS IN MEDICINE AND SURGERY, AND EXAMINATION FOR THE DIPLOMA IN MIDWIFERY.

The Examination for the M.D. comprises the subjects recommended for study during the second period.

The Examination for the M.Ch. comprises Surgery, including Operative and Clinical Surgery.

The Examination for the Diploma in Midwifery comprises the Theory and Practice of Midwifery and the use of obstetrical instruments and appliances.

Both Honour and Pass Examinations are held in September. The Examination held June is a Pass Examination.

(See Advertisements of Queen's Colleges, Belfast, Galway, and Cork.)

Official regulations may be obtained from G. J. Stoney, Esq., Queen's University, Dublin Castle.

## ROYAL COLLEGE OF SURGEONS IN IRELAND.

(For names of Professors in the College see Advertisement of the School of Surgery.)

The arrangements for granting the licences of this College are in an unsettled condition. A new system of examination had been decided upon by its Council and promulgated, and one examination has been held under it. The bringing of this arrangement into universal application has been since deferred, and we are not aware, nor do the printed regulations inform us, upon whom the new system is or is not compulsory. Within the last fortnight the Council has announced that examinations will be held on the 30th of November and 14th of December next, which is explained in detail in our advertising columns.

### The examination for

LETTERS TESTIMONIAL, OR THE L.R.C.S.I., is divided into two parts, known as the first and second halves.

### The junior class must produce certificates of—

Three courses of lectures on Anatomy and Physiology, three on Practical Anatomy, with dissections, two on Chemistry, one on Materia Medica, one on Botany, and one on Forensic Medicine. This class is examined in Anatomy, Physiology, and Materia Medica.

### The senior class must produce certificates of—

Three courses on Surgery, one on Practice of Medicine, and one on Midwifery; also, attendance on a recognised hospital for three winter and three summer sessions. This class is examined in Surgery, Operative Surgery, Practice of Medicine, and form of Prescription.

The fees are: 10s. for Preliminary Examination; £5 5s. as registered pupil of the College; £5 5s. for the Junior Class Examination, which is not returned in case of rejection, but is allowed in the fee for his second examination; £15 15s. for the Senior Class Examination—total £26 15s.

Every candidate rejected at the quarterly examination is required to pay to the College the sum of £2 2s. on applying for re-examination.

### MIDWIFERY.

After passing the L.R.C.S. the student is admitted to examination for the diploma in Midwifery upon producing a certificate of one course on Midwifery and Diseases of Women and Children; a certificate that he has attended a lying-in hospital for six months; and a certificate that he has conducted thirty labour cases at least.

Candidates are examined on the Organisation of the Female, the Growth and Peculiarities of the Fetus, the Practice of Midwifery, and the Diseases of Women and Children.

The candidate pays £1 6s. for the Midwifery diploma provided he takes it out within one month from the date of his Letters Testimonial; after that date, £2 2s.

Official information may be had on application to Mr. J. rennen, Royal College of Surgeons, Dublin.

KING AND QUEEN'S COLLEGE OF PHYSICIANS  
IN IRELAND.

## REGULATIONS RELATIVE TO THE LICENCE IN MEDICINE.

EXAMINATIONS are held on the second Tuesday and Wednesday in each month.

The name of every candidate, together with his schedule and the required documents, must first be submitted to the College on the first Friday in each month, and no name can be received later than the Monday previous.

REGULATIONS RESPECTING THE LICENCES IN MEDICINE AND  
MIDWIFERY.

Candidates who have not obtained some medical or surgical qualification must give proof of four years' study, of having passed a Preliminary Examination in Arts; and of having studied Anatomy and Physiology, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica, Botany, Medical Jurisprudence, Practice of Medicine, Pathology, Surgery, and Midwifery.

Of having attended a Medico-Chirurgical Hospital, with Clinical Lectures, for twenty-seven months.

Of six months' Practical Midwifery at an hospital, or other satisfactory evidence of having attended Practical Midwifery.

Testimonials of character from two registered physicians or surgeons are also required.

A Candidate who has already obtained a medical or surgical qualification in Great Britain and Ireland is required to fill up a schedule; but he is only required to produce his diploma or certificate of registration, and the certificate of Practical Midwifery, and testimonials as to character.

The examination is conducted partly by written questions, partly *visd voce*, and partly clinical, and divided into two parts:

First Part—Anatomy, Physiology, Botany and Chemistry. Second Part—Materia Medica, Practice of Medicine, Medical Jurisprudence, and Midwifery.

Gentlemen who have passed the first portion of the examination for the L.R.C.S.I. or M.R.C.S.E. are exempted from the first part of the examination.

Candidates who have been five years in practice are not required to undergo the written or clinical portions of the examination.

## REGULATIONS RELATIVE TO THE LICENCE IN MIDWIFERY.

Examinations for the Licence in Midwifery are held on the day after those for the Licence in Medicine.

Candidates not being Licentiates will be admitted on the following qualifications:—The Degree or Licence in Medicine or Surgery, with a Certificate of six months' Lectures on Midwifery, with six months at a recognised lying-in hospital or of having attended Practical Midwifery for six months at a recognised lying-in hospital, or other evidence of having attended Practical Midwifery.

## FEES FOR LICENCES.

The Fee for the Licence in Medicine is £15 15s.

The Fee for the Midwifery Licence is £3 3s.

The Fee for the Licences in Medicine and in Midwifery, if taken out within one month, £16.

Further information and blank schedules may be obtained by application, personally or by letter, to Dr. J. Magee Finny, the Registrar, College of Physicians, Kildare Street, Dublin.

## THE APOTHECARIES' HALL, IRELAND.

## THE ARTS EXAMINATIONS

Will be held at the Hall four times in the year, viz., the third Thursday in the months of January, April, July, and October, at the hour of twelve o'clock noon. It will be conducted by means of printed papers and *visd voce* by special examiners (Graduates in Arts of the University of Dublin), under the supervision of the Court of Directors. The answers to the papers will be required in writing.

## THE PROFESSIONAL EDUCATION AND EXAMINATIONS.

Every candidate for the Licence to Practise must produce certificates—

1. Of having passed an Examination in Arts previously to professional study.

2. Of being at least twenty-one years of age, and of good moral character.
3. Of Apprenticeship to a qualified Apothecary, or *Practical* Pharmacy with an Apothecary for three years subsequent to the Examination in Arts.
4. Of four years' Professional Study.
5. Of having attended the following courses, viz.:—Chemistry, One Winter; Anatomy and Physiology, Two Winters; Demonstrations and Dissections, Two Winters; Botany and Natural History, One Summer; Practical Chemistry, Three Months; Materia Medica, Three Months; Principles and Practice of Medicine, One Winter; Midwifery and Diseases of Women and Children, Six Months; Practical Midwifery (attendance upon twenty cases); Surgery, One Winter; Forensic Medicine, One Summer; Instruction in Vaccination.
6. Of having attended a recognised hospital during two winters and two summers.
7. Of having performed the operation of Vaccination successfully under a recognised Vaccinator.

The Examination for the Licence is divided into two parts: The First Part comprehends Chemistry, Botany, Anatomy, Physiology, Materia Medica, and Pharmacy.

The Second—Medicine, Surgery, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Hygiene.

## THE PROFESSIONAL EXAMINATIONS

Will be held *quarterly*, on the first and second Mondays in January, April, July, and October.

The First Part, for Junior Students, on the first Monday, at twelve o'clock noon, and on the Tuesday and Wednesday succeeding at the same hour.

*Subjects*:—Chemistry and Botany, Monday; Anatomy and Physiology, Tuesday; Materia Medica and Pharmacy, Wednesday.

The Second Part, or Pass Examination, for Senior Students, on the second Monday, at twelve o'clock noon, and on the Tuesday and Wednesday succeeding, at the same hour.

*Subjects*:—Medicine and Surgery, Monday; Midwifery and Diseases of Women and Children, Tuesday; Forensic Medicine and Hygiene, Wednesday; Clinical Examination, Thursday.

The first two hours of each day will be devoted to writing answers, and, after that, two hours to an oral and practical examination.

Doctors of Medicine and Licentiates of a College of Physicians or Surgeons who have served an apprenticeship, or the required term at *Practical* Pharmacy, may obtain the Licence by undergoing an examination—the former in Pharmacy (a) and the latter in Medicine and Pharmacy. Licentiates of the London Society of Apothecaries are admitted *ad eundem*.

An *Honour* Examination for apprentices is held in the first week in May, upon some subject of Medical or Pharmaceutical Chemistry, and a Prize of Five Guineas is awarded to the successful competitor.

## MEDICAL SCHOOLS AND HOSPITALS.

THE Clinical Hospitals of Dublin are 10 in number, exclusive of the Cork Street Fever Hospital, the Children's Hospital in Pitt Street, the Dublin Eye and Ear Infirmary in Ely Place, and other special institutions. To some of these institutions Medical Schools are attached, others, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies, while others again are without any special connection with any school. While, however, such affiliation of a school and hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is competent to attend

(a) The Examination in Pharmacy will include Practical Pharmacy, Pharmaceutical Chemistry, Toxicology, Medical Botany, and the British Pharmacopoeia. A full course of instruction on most of these subjects is delivered by Mr. C. R. C. Tieckborne, F.C.S., Chemist to the Apothecaries' Hall.

any hospital and any school he wishes. The restriction which rendered it obligatory for candidates for the medical degrees of the University of Dublin to attend Sir Patrick Dun's Hospital was recently abolished, and perfect "free trade" thus established.

**SCHOOL OF PHYSIC AND SIR PATRICK DUN'S HOSPITAL.**—The Medical School of Trinity College is one of the largest and most important, and in it the education of a large section of the Irish Medical Profession is carried out. It is especially frequented by those students who intend to take the Arts Curriculum of the University, but is freely open to, and largely availed of by other students. It is under the immediate supervision of the Reverend Professor Haughton, the Medical Registrar of the University, and the names of its Professors will be found appended to the advertisement in our Journal, and to the official regulations of the University. Two Medical Scholars are elected annually by the Board of Trinity College, at an examination held at the end of June, subject to conditions stated in the College Calendar. Each scholarship is worth £20 per annum, and is tenable for two years. The Professors of the School of Physic give three exhibitions annually, amounting altogether in value to £40, subject to conditions prescribed by the Professors themselves.

Sir Patrick Dun's is the hospital attached by Act of Parliament to the School of Physic, and officered by the Professors of that school. It was for many years a purely medical hospital, but is now a large medico-chirurgical hospital, with a Midwifery Maternity attached. (*For Names of Professors and further information see Advertisement.*)

The ROYAL COLLEGE OF SURGEONS SCHOOL is situated within the walls of the College, and is under the superintendence of the Council, who appoint the Professors. The Introductory Address will be given on the last Monday in October by Dr. Mapother. The Professor of Physiology commences his course with a series of twelve lectures on Comparative Anatomy—free to the public. The dissecting-rooms have been recently much enlarged. Prizes in Anatomy and Physiology, and Surgery, will be awarded at the end of the winter session. (*Full particulars will be found in the Advertisement.*)

The CITY OF DUBLIN HOSPITAL has been hitherto more closely connected with the College School than any other hospital. It is situated in Upper Baginbun Street, about ten minutes' walk from the Royal College of Surgeons. The hospital contains 104 beds, and accommodates about 800 intern patients annually. There are special wards for ophthalmic and aural diseases (on which subjects a special course of lectures is delivered), and for diseases of children. A new wing has been lately opened for the reception of fever and other infectious diseases. The "Purser" Studentship of £20 per annum (with apartments) is obtainable by competitive examination by all students; numerous prizes and medals are given, and special certificates are granted. (*For full information see Advertisement.*)

The CATHOLIC UNIVERSITY SCHOOL is situated in Cecilia Street, about ten minutes' walk from the University itself in St. Stephen's Green. (*Full particulars will be found in the Advertisement.*)

The hospitals most closely connected with this School are St. Vincent's, in St. Stephen's Green; the Mater Misericordiae Hospital, in Eccles Street; Jervis Street Hospital; and House of Industry Hospital.

ST. VINCENT'S HOSPITAL was established in 1834 by the Sisters of Charity, some of whom had studied the system of the Parisian hospitals, after which it was modelled. The ward for "*Enfants Malades*" is an interesting feature. The hospital has over a hundred beds constantly full, and each sister has charge of about twelve patients. In connection with it a Convalescent Home was established four years since at Stillorgan. The clinical instruction in medicine and surgery is given by Dr. Quinlan, Dr. Mapother, Dr. O'Leary, and Dr. Cryan. Senior and junior prizes in clinical medicine or surgery are awarded at the end of the winter session.

The Introductory Lecture will be delivered by Dr. Mapother in the beginning of November. (*See Advertisement.*)

The MATER MISERICORDIAE HOSPITAL is the largest of the Dublin hospitals, and is intended to be much extended. It is situated at the northern side of the town.

There are three resident pupils appointed every six months. Good lodgings can be had very cheap close to the hospital. Prizes to the value of £30 are awarded at the end of the winter session for the best reports on the cases under treatment in the hospital. (*See Advertisement.*)

JERVIS STREET HOSPITAL is one of the oldest established charitable institutions in Dublin, having been founded in 1721. It is situated in a part of the city not otherwise provided with hospital relief, and which, from its commercial character, supplies the hospital with an abundance of surgical cases. Like St. Vincent's Hospital, its nursing arrangements are under the charge of a community of nuns. The hospital being found inadequate to the demands upon it, is about to be re-built. (*Full particulars will be found in the Advertisement.*)

The LEDWICH SCHOOL was founded in 1810 by the well-known Dr. Kirby, and since then has fully sustained its prestige under the management of the Messrs. Ledwich and Mason, after the former of whom it is named. It is situated in Peter Street, not five minutes' walk from the College of Surgeons, the Meath, and Mercer's Hospital, and in the same street with the Adelaide Hospital and the Anglessea branch of the Coombe Lying-in Hospital, and ten minutes' from the Catholic University School, the School of Physic, and the City of Dublin Hospital.

Dr. Kelly, Surgeon to Jervis Street Hospital, will deliver the Introductory Address, on Monday, the 2nd of October. (*For full particulars see Advertisement.*)

MERCER'S HOSPITAL enjoys a high reputation as a surgical hospital, and is specially resorted to in cases of accident. It is situated equidistant from the Ledwich School and the College of Surgeons, and not far from the School of Physic, and numbers amongst its staff professors in both the former schools. The great majority of the students of the Ledwich School receive within the walls of Mercer's their hospital teaching. (*Full particulars will be found in the Advertisement.*)

The CARMICHAEL SCHOOL is situated in North Brunswick Street.

The various lectures are now delivered, and the dissections carried on in the new building, which the munificence of the late Surgeon Carmichael has given to the proprietors.

The close proximity of this school to several of the Dublin clinical institutions, and its intimate connection through its teachers with the Richmond, Whitworth, and Hardwicke, as well as Jervis Street Hospitals, ensures equal opportunities to the pupils of becoming thoroughly acquainted with the more immediately practical part of their profession.

Arrangements have now been completed for rendering more available the Carmichael premium bequest, which enables the proprietors to distribute prizes to the amount of £60 yearly; and the Scholarship, value £15 yearly, which the friends of the late Dr. Mayne founded in his name, is allotted to the termination of the winter session.

To fill the vacancies which have recently occurred on the staff, the following appointments have been made:—

To the Chair of Chemistry—Mr. C. R. C. Tichborne, Ph.D., F.C.S., Chemist to the Apothecaries' Hall, &c., &c.

To the Chair of Anatomy—Mr. William Thomson, M.D. Q.U.I., F.R.C.S.I., Surgeon to the Richmond Hospital.

To the Chair of Forensic Medicine—Mr. G. M. Foy, F.R.C.S.I. (*See Advertisement.*)

RICHMOND, WHITWORTH, and HARDWICKE HOSPITALS, North Brunswick Street.

These Hospitals contain 312 beds—110 for surgical cases, 82 for medical cases, and 120 for fever and other epidemic diseases. During the past year 2,315 patients were admitted, presenting to students the most ample opportunities for studying every form of disease.

The Dispensary establishment for the medical hospitals is now carried on in a large new building erected for the purpose.

The Truss establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. In the examination of the applicants, the student is afforded the facility not only of seeing all the varieties of hernia, but of acquiring a knowledge of the several diseases that may be confounded therewith.

Eight resident clinical clerks are appointed each half-year, and provided with furnished apartments, fuel, &c., &c.

These appointments are open not only to advanced students, as formerly, but also to those who are qualified in medicine or surgery. A house-surgeon, who receives salary, is elected every second year.

The Richmond Institution for the Insane, containing 1,000 beds, adjoins these hospitals, affording every facility for the study of mental diseases.

The Carmichael School of Medicine, in which all the courses of lectures required by the different colleges are delivered, adjoins these hospitals; the student is thus furnished with every facility for completing his professional education.

DR. STEEVENS' HOSPITAL AND SCHOOL are situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, and therefore occupy a position of their own, far removed from the other medical institutions.

Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane.

There is accommodation for residence of seven surgical and four medical residents; besides whom the resident-surgeon receives house pupils. The fees payable for the privilege of residence are 21 guineas, winter; 15 guineas, summer six months; students have apartments, coal, gas, and furniture.

Accommodation outside the hospital, in the neighbourhood, is arranged by the hospital authorities. (See Advertisement.)

#### PRIZES.

Three Cusack Medical and Exhibition, of £8, £5, £3; two Midwifery Assistants, £30 each; one Medical Clinical Prize, £10 10s.; one Surgical Prize, £10 10s.

As we have said, certain hospitals have no special affinity with any college or school. Of these are the Meath and Adelaide Hospitals.

The MEATH HOSPITAL, which is also the public infirmary of the county of Dublin, containing 120 beds, and now in the 119th year of its existence, ranks among the oldest of the charitable institutions of this city. It is situated on the southern side of the city, upon about three acres of ground, formerly called "The Dean's Vineyard." The original Meath Hospital, situated on the Coombe, was opened in 1753. The foundation-stone of a new Meath Hospital, on the Coombe (now the Coombe Lying-in Hospital), was laid out by Lord Brabazon, 10th October, 1770; this hospital was, in 1774, constituted the County Dublin Infirmary, by Act of Parliament. The present building, in Heytesbury Street, was opened in 1822, since which time the building has undergone considerable enlargements and improvements. In 1830 the theatre for operations and lectures was erected. In 1852-3 the Collis Wards were added as a memorial to Maurice Collis, twenty-five years surgeon to the hospital. In 1865 the "Smyly Ward," built for the special accommodation of children, was opened by the Lord-Lieutenant, Lord Wodehouse. (Full particulars as to the medical and surgical staff will be found in the Advertisement.)

The ADELAIDE HOSPITAL is in Peter Street, next door to the Ledwith School, and within a few minutes' walk of the College of Surgeons and the Universities. From the 1st of October the physicians and surgeons will visit the wards, and give instructions at the bedside, at the advertised hours.

There are fever wards apart from the hospital, and two wards for infants and children. Special hours are devoted to clinical instruction in the Diseases Peculiar to Women, the Diseases of the Eye, and Cutaneous Diseases, and students are individually instructed in the use of the Stethoscope, Ophthalmoscope, Laryngoscope, and Microscope. Two resident pupils are selected half-yearly. Prize examinations are held at the termination of the session; in addition a prize of the value of £5, founded by Dr. Knaggs, of Australia, a former pupil of the hospital, is awarded in June, annually. (See Advertisement.)

#### SPECIAL HOSPITALS.

The Special Hospitals of Dublin are the Westmoreland Lock Hospital, Cork Street Fever Hospital, Pitt Street Children's Infirmary, the Dublin Eye and Ear Infirmary, St. Mark's Ophthalmic Hospital, and the National Eye and Ear Infirmary.

The PITT STREET CHILDREN'S INFIRMARY is situated close to Mercer's Hospital and the College of Surgeons. It was

founded to provide treatment specially for children, and to teach that special branch of disease. Dr. Moore and Dr. Churchill, senior, are the medical officers. (See Advertisement.)

The DUBLIN INFIRMARY FOR DISEASES OF THE EYE AND EAR was founded two years ago. It accommodates eighteen beds, and has for its chief surgeon Dr. Jacob, formerly Ophthalmic and Aural Surgeon to the City of Dublin Hospital; and for its consultants, Mr. Porter, Surgeon to the Queen in Ireland, Dr. Evory Kennedy, and Dr. John Cronyn. At the Dispensary every form of disease of the eye and ear is seen thrice weekly, and operations are performed on Tuesdays and Thursdays at four o'clock. Particulars of fees for attendance may be had from Dr. Jacob. (See Advertisement.)

ST. MARK'S OPHTHALMIC HOSPITAL AND DISPENSARY FOR DISEASES OF THE EYE AND EAR.—This is the oldest and largest special ophthalmic hospital in Dublin, and was founded by Sir William Wilde. Instruction is given on the mornings of Mondays, Tuesdays, Thursdays, and Fridays, from eleven to one o'clock, and operations are performed on Wednesdays and Saturdays from eleven to one o'clock. A surgeon resides in the institution, and receives a salary of £30, besides rooms, gas, coal, &c. (Full particulars will be learned on reference to the Advertisement.)

COOMBE HOSPITAL.—This hospital was founded in 1826, but it was not till 1867 that it was incorporated by royal charter, which enables its medical officers to issue diplomas qualifying the holders to practise midwifery. This hospital is situated in the centre of a district densely populated by the lower orders, and thus affords the amplest opportunities for practice. It accommodates about 600 labour cases within its walls, while those attended as externs amount to nearly double that number. Moreover, the chronic ward for the reception of cases of the diseases of females gives admission to about eighty patients annually. Its wards are in the charge of Dr. Ringland and Dr. Sawyer, as masters, and Dr. A. H. Ringland as assistant-master, whilst the chronic ward for the diseases of females is under the charge of Dr. Kidd, the obstetric surgeon of the institution. The fee for attendance is £4 4s. for six months as extern, and £10 10s. as intern pupil. During that period the student attends on a given night in each week, or oftener, if circumstances permit, and takes charge in his turn of any cases that may be admitted to the labour wards, or may call for his assistance outside. An annual examination is held in May and November, at which prizes of considerable amount are awarded, and certificates of good answering granted. Two paid resident pupil midwifery assistantships, and a paid clinical clerkship under the obstetric surgeon, are obtainable annually by competitive examination, for which all pupils who have obtained their midwifery diploma are eligible.

CORK OPHTHALMIC AND AURAL HOSPITAL (Special Department for Diseases of the Throat), founded 1863.—Average extern attendance about 2000; contains twenty beds. It is supported by voluntary subscriptions, and a small corporation grant, its gross income being about £300 a year. The beds are partly self-supporting, a few being free.

#### THE QUEEN'S COLLEGES.

THESE three important institutions are the special schools of the Queen's University, and are situated in Belfast, Galway, and Cork. They receive a large subvention from the public funds, and are provided with every facility for the education of their students. It is essential that every candidate for the medical or surgical degrees of the Queen's University shall have attended courses of lectures in Modern Languages, Natural Philosophy, and at least two medical subjects, in one of the provincial colleges, so that a brief residence within a Queen's College during a portion of one of the years of medical study is compulsory upon all candidates for the licences of this University.

#### REGULATIONS COMMON TO ALL THE QUEEN'S COLLEGES.

*Students.*—Students are either matriculated or non-matriculated.

Candidates for degrees, or for scholarships, exhibitions, or prizes, must pass a matriculation examination.

Non-matriculated are permitted to attend the lectures of any of the professors without being required to pass the matriculation or any other examination.

*Matriculation Examination* will commence in the beginning of October and November.

The subjects in which candidates will be examined are these :—

Greek :—Grammar.

Any one of the following authors :—

Homer—*Iliad*, Books I. and II. Xenophon—*Anabasis*,

Books I. and II.

Latin : Any one of the authors.

English :—Grammar.

Outlines of Grecian History. Outlines of Roman History.

Outlines of Ancient and Modern Geography.

Mathematics : Arithmetic, Algebra, and Euclid—Books I. and II.

The Matriculation Examination is held at the commencement of the first term of each session; but additional Matriculation Examinations are held before the close of the term.
